1425. OT: Reconcile Qs using SPICE

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-30 01:23:47 UTC
From: John - KD5YI <groups5munge@verizon.net>
Message-ID: <Ds0%e.11094$WT3.7174@trnddc03>
Source record: 69821

Forgive the OT posting, but I know a lot of RF experts hang out here.

I am trying to learn about Q. I know there is a difference in component Q and circuit Q. To study this thing, I am using SPICE so that I will have no instrument loading to affect my setup. I can make things as perfect as I wish, almost.

My problem is that I cannot reconcile the two ways of obtaining Q:

1. Q = X/R (reactance divided by resistance)
2. Q = Fo/BW (resonant frequency divided by bandwidth)

In spice, I have a 1V source, one end connected to ground and the other end applied to a series string composed of L = 24.833 mH, 458 ohms, and 102 pF and then to ground. Essentially, I have a series circuit consisting of a source, inductor, resistor, and capacitor. The resonant frequency should be 100 kHz.

Using SPICE, I examine the current in the loop. I find that the current 6dB down points are about +/- 2.5 kHz away from 100 kHz. This is a Q of about 20.

But, the reactance is about 15.6 kohms and the resistance is 458 ohms, so the calculated Q is about 34.

Can someone explain where I'm going wrong here?

Thanks.

The OED is fine if you include the historical tag citations,
contemporary dictionaries (unless you are arguing from the perspective
of a 19th century monk) allow:

1. An extreme form of skepticism that denies all existence.
2. A doctrine holding that all values are baseless and that nothing
can be known or communicated.

>>>So in what context do we contain poorly understood rules and
>>>perceptions? How do we speak of them?
fits perfectly fine in the second context and dovetails with your
rather amorphous logic. In fact, this second usage is almost your
manifesto here - with the aforementioned insurance policy against
damnation.

When I learned that the BBC wasn't available on shortwave, I made no effort to listen to it on the Internet. The magic was gone. I could no longer take my battery-powered HF radio out in the country or in my car (no, I don't have satellite radio) and listen to BBC. The programming was fantastic. What a loss.

There goes another thing I really enjoyed.

Thanks, Gene.

Then my misunderstanding is with Decibels (or SPICE) instead of Q. You are correct that, if I check the bandwidth between the 3dB *current* points, the numbers come out about right. However, I thought 3dB was a power thing and 6dB was a current (or voltage) thing. In any case, if I use the 3dB down points of either voltage or current, it works out as calculated. So I checked the current at the 3dB points and that put the Q very close to the X/R point.

Thanks for your help.

John

Source record: 69682

Richard,

Everybody says that thickening the antenna conductor increases the bandwidth. And indeed it does.

But nobody ever says by how much the bandwidth is increased.

I think this is because bandwidth is increased by such a small proportion that it's not worth the trouble and expense of erecting another antenna. Otherwise everybody would have giant, unsightly, neighbor-offending, cages in their back yards. But they don't.

I have a program, DIPCAGE2, which calculates the increase in bandwith due to increase in dipole diameter which demonstrates this disappointing point.

I would like confirmation that my calculations are correct. Do you have, or know of, any reliable measurements of bandwidth versus dipole conductor diameter. One serious, accurate example might be good enough. These days I don't have the facilities to make measurements myself.

It doesn't matter how bandwidth is defined but I am not happy with the usual 'SWR/bandwidth' definition because of unreliability of SWR meters plus the misplaced confidence in them.

In practice, accurate knowledge of antenna bandwidth is not of great use since the system operating bandwidth is affected by the transmission line and matching network, if there is one. I don't know why I'm bothered about it! But I WOULD like to see an appropriate degree of importance attached to the subject on these walls.

Reggie, G4FGQ.

OK, but that tickly feeling consists of many spikey pulses, and from
Fourier, pulses consist of a whole series of higher order frequencies.
However, this could be relevant, some scientist in Florida studying
lightning has theorized that the strike is instigated by cosmic
radiation, more specifically gamma ray bursts from blackholes. It kind
of makes sense because if the CR creates an ionization trail in the
atmosphere, this is a good initial conductive channel for the cloud's
potential to drive a current into a suitable ground point. Awesome.

I think it is whatever you want it to be because it is a transformer.
Varying Rs would only affect the pattern.

In standard antenna parlance, the "pattern" is unaffected (aside from
magnitude, and then only by consequence of mismatch) by
transformation.

Hi Mark,

Perhaps his SPF is higher than his IQ.
Two problems I see with this speculation:
1. Cosmic Rays don't follow random paths;
b. Cosmic Rays don't travel at the speed of a falling greyhound bus;
iii. There are more Cosmic Rays at the magnetic poles where there is
little lightning, than in Florida where they are aplenty.

there actually is a clear air current that flows all the time, you can
actually draw power from it with a relatively small 'antenna'. in fact,
many years ago one of the 'popular' magazines published plans for a motor
that ran off the clear air electric field, you just had to be sure to
disconnect it before a thunderstorm came through.

There's almost certainly nothing the matter with it.

You can't expect a small QRP magloop to work as well as a 1/2-wave
vertical with 100 watts.

What makes you think it is not working as well as it ought to? What
have you compared it with?

Cecil, W5DXP wrote:
"Is the graph impedance looking into 1/2 of the dipole?"

I only quoted from the plot for tthe whole dipole in free-space.

The graph on page 345 has two traces:

Zo, or antenna average surge impedance, ZA, for a balanced, center-fed dipole in free-space, which is found to be a function of the antenna thickness=

ZA = 276 log 1/P

The other formula is also plotted. It is for a vertical rod against ground. It has exactly 1/2 the resistance of the dipole.

For peripheries larger than 0.25 wavelength, Bailey notes that surge impedance departs from the formula. For smaller peripheries, the plots are almost straight lines on the scale used. Peripheries are plotted with log spacings. Impedances are plotted with linear spacings.

Best regards, Richard Harrison, KB5WZI

This idea does not appear to be the product of some wacko professor in some obscure junior college. There is a fairly large amount of work ongoing around the world. The first scientific paper with a detailed analysis of a possible role for cosmic rays in lightning generation appears to be from Russia, in 1992.

The unsolved mystery with lightning generation is how it can happen at all. The breakdown strength of air is something like 2 megavolts per meter. No one can come close to finding this sort of field strength in clouds, even the violent clouds associated with thunderstorms. At the same time, it is now well documented that there are gamma-ray bursts that appear to be well correlated to lightning strikes. Gamma-ray generation requires extremely energetic relativistic electrons. Again, there is no clear mechanism for generation of these gamma-rays in ordinary atmospheric processes.

The proposal is that the violent atmospheric processes establish electric fields well beyond normal calm atmospheric levels, but still insufficient for spontaneous breakdown and lightning discharge. The cosmic rays act as a trigger to cause the breakdown and discharge.

I don't have a dog in this fight; I am merely reporting an overview of what I have read.

John,

The generic definition of Q is the ratio of energy stored over a cycle to energy dissipated over a cycle. Thus it makes sense to look at energy or power as the entity under analysis. Width of a resonance peak is commonly defined at the half-point, i.e., 3 dB down from the peak.

If you wish to look at current, then the magic number for bandwidth definition is 70.7% of peak current. This number will be found in any number of books, including Terman.

It sounds like you are slightly confused about the definition and application of dB. It is traditional that the basic definition of dB is:

dB = 10 * log10 (P2/P1)

At the same time, a very common adjunct is:

dB = 20 * log10 (I2/I1)

or

dB = 20 * log10 (V2/V1)

As long as the resistance does not vary, it will not matter whether you consider dB to represent a power ratio or a voltage ratio or a current ratio. The numerical result will be the same.

the breakdown strength of air is more like 500kv/m.

the well documented explanaition for how lightning works doesn't expect to break down the whole distance in one shot, as noted that would be impossible given the charges available. that is where the stepped leader comes in that collects charge and advances in steps of 50-100m at a time. this process is easily observable and fairly well understood.

there is some speculation that sprites or jets above large thunderstorms may be either caused by or the cause of high energy discharges from storms. these are relatively recently discovered events and are still being explored but appear to be discharges from the top of thunderstorms up into the ionosphere resulting in aurora like, but very short, visible effects.

1. Never eat at a place called Moms.
2. Never buy an antenna that has the word "Miracle" in the name or description.

Other things to avoid pertaining to antennas:

"This new principal cannot be modeled in existing programs because of their limitations"

Claims that a particular geometry has magical properties.

E/H CFA or some other alphabet soup descriptions coupled with any of the above.

Things to be sceptical about:

Any antenna that touts take off angle and F/B ratio as primary features.

Low SWR from DC to Daylight

Any 1/4 wave virtical that needs no radials because of some wizzbang loading system.

Special gadgets in the feedline that makes it become a radiating element.

This by no means the extent of things to watch out for. A real education is to read the adds for CB antennas, then when the same claims are seen for a ham antenna put the credit card back in your wallet.

P.T. Barnum should have sold antennas. His statement would then have been "There is a sucker born every 30 seconds"

Reg,

I have used cages in the past. Looking at my notes, using 12" (I leave the conversion to you in retaliation for having to convert to metric using your programs) diameter PVC pipe slices. 6 wires spaced at 60 degree separation, resulted in a bandwidth of 316 KHz on 75 meters when mounted 40 feet above ground.

The wire diameters and wire types had almost no effect on the bandwidth, which was defined at the 2:1 SWR points. Using electric fence wire, for example, resulted in 314 KHz.

Anecdotally, it was the quietest antenna I have ever used.

Reg, G4FGQ wrote:
"When the circumference of the antenna rod is one wavelength, Zo = 0."

Bailey adrees with Reg. I was remiss in not quoting Bailey`s caveat. The formula does not hold for circumferences greater than one-quarter wavelength.

Bailey notes that uniform cross section conductors don`t have ubiform impedances throughout their lengths. Zo is inversely proportional to capacitance per unit length. Zo is lower at the antenna feedpoint than at its conductors` middles. At the tips or open ends of antennas, Zo is low. This is explained by the concentration of electric force lines at the open end.

Variation of Zo along an antenna need not deter one from finding a workable average of surge impedance. Bailey has determined this to be:

276 log 1/P, where P=circumference of the conductor in wavelength, for circumferences of less than 1/4-wavelength.

For practical lengths of center-fed dipoles, the feedpoint impedance is determined by combination of incident and reflected waves. Bailey has worked out these for resonant lengths between 1/2 and 5 wavelengths. I posted these long ago. But, for infinite length, Zo must prevail, as no reflection will ever return.

Best regards, Richard Harrison, KB5WZI

Yes.

Actually, I understand the equations. I think my confusion is the
application of them. I was assuming I needed to measure the frequency at the
-6dB points because I was plotting current rather than power.

That's where I went wrong.

Thanks again.

Cheers,
John

Whatheheck is a takeoff angle anyway? From my limited experience with modeling programs, and anecdotal personal experience, that signal I'm putting out takes off at all angles. Well, at least 180 degrees worth.

It's stronger at some angles than others tho'.

But it doesn't have one angle.

Thanks for the explanation, Cecil. I do have to say that the 2nd order fractal is what I consider a real fractal. The first order serves well enough as a basis for fractals, and goes some way to explaning them, but tends to be such a common thing that just about any non-linear antenna could get the moniker.

I think it opens up a new alternative to the lightning rod. Might some
form of radiation shielding be just as effective instead? If there are
no air ionization paths of cosmic origin under the shield then the
lightning has no place to start? Six inches of lead over the antenna
tower doesn't seem right though... perhaps some type of plastic
umbrella? Does anyone know if mountain top radar domes are hit less
often than other aerials?

--- on the heady topic of "Re: UWB Antennas, why these shapes?"

Bailey talks about bandwidth vs thickness. A first speculation is that
the increase in bandwidth as the conductor is made thicker is a
consequence of the longer diagonal dimension. One way to determine BW
would measure the antenna constants to get the Q. Then the Q is used
to calculate bandwidth just as in a parallel tank. However, a real
antenna has many unpredictable factors which affect it (for example
feed capacitance) such that other resonnances can appear close to
natural resonnance. These would affect bandwidth and mess up the
parallel tank analogy. Sorry can't help there...

I think that the greatest thing I ever saw was a antenna enhancement
attachment that a friend of mine was conned into selling. It looked just
like the gamma match from a Cushcraft Ringo antenna. This gadget was
fastened to your antenna with a hose clamp, had a ring shapped element
and a wiper arm just like the Ringo. To the credit of the developer he
atleast said that he didn't know just what his gadget would do, why the
Ringo (not mentioned by name) had one but what could hurt by enriching

his bank account.

Still laughing about it.

Dave WD9BDZ

BTW: This was a CB radio thing, not Amateur Radio.

Figured as much. You might want to try the loop in a horizontal configuration
for omnidirectional work. You'll probably find that you can operate it horizontally
just a few inches above the ground although I recommend a couple feet.

Regarding the miracle Whip antenna.

1. It isn't a miracle.

2. It does not work "great"

3. However, it gets a signal out within its abilities. A good operator
can work a lot of stations with one.

4. The folks who build and sell it are pretty honest about it's
performance. The only part I have an exception with is their performance
being rated in regards to SWR. But they put it right out there, so no

one can say the information wasn't available.

5. Do we really think that a person believes that the antenna is going to be some kind of top performer? It's a niche antenna.

6. Is it better to have a modest setup, or no setup at all? Seems like a nice way to have a quick setup and operating station in a hotel room or while traveling. Maybe even for mountain topping.

It isn't a very good term then. It makes it sound as if it is the angle at which the RF "takes off" at, when in fact it is not.

And it seems that a lot of people get really hung up on that, thinking that there is some kind of blob of RF that leaves the antenna at X angle. Even when people "know" that isn't the case, we still see them thinking that way.

Maybe we should start using the term "Takeoff Azimuth" too? ;^)

I have used one for 1 year now so this is my opinion:

It is a fun thing to play with but off course there are limitations. It's
exactly as good as its size, which of course is the case with all antennas.
It's quite good made if you look inside the box. It works quite well for
recieving on 80 and 160 as well.

It requires no counterpoise and actually if you try to improve it with a
good RF-ground it will not tune.... Is there someone out there who can
explain this to me..... ;-)

John, OOPS... Like they said in Planes, Trains and Automobiles; "You're going the wrong way!"

With all due respect, I suggest you do not understand the equations and how to apply them. Don't feel bad, though, this is a very common problem. You fell into a common trap. I have for years posed a question to new Engineers:

Why is a "Voltage dB" twice as big as a "Power dB" ?. .. Sorry Alex.

Just to see if they really understand and have some fun as well... a little good natured hazing, if you will.

What Gene says is 100%, but I clarify. This is the best way I know how to explain this, so if there is a better way, so be it...

Just a little background:

The decibel is one tenth of a Bel. Just like kilowatt is 1000 watts and meg ohm is 10^6 ohms. It is a prefixed unit. The Bel (named after good ole' Alex Grham) represents a Power ratio of 10:1 (or 1:10) PERIOD! NO IF's AND's or BUT's. (note that here is nothing in there about voltage or current)

[That's also why the "B is capitalized and the "d" isn't]

You can't "legally" talk about dB in voltage. Sorry, it is ABSOLUTELY WRONG! [[NO flames here, let me explain]] HOWEVER, strange beings that we are (and at some times smarter than at others), we have accepted, as a common practice, the use of dB when referring to voltage and current ratios because we, knowing about math and electronics, understand that there is a relationship between power and these quantities (the all too familiar and confusing formulas).

Now, approaching your issue...

IF we have some circuit and make two measurements and the difference happens to be 3 dB, we had to make that measurement in some way. _IF_ we make that measurement with a voltmeter, THEN we use the "dB Volts" formula and we will get an answer of 3 dB. _IF_ we use an ammeter...you know the rest. Uh, here you expect me to say _IF_ you use a watt meter..., but I wont, because you can't measure power. This is from the "You can't get there from here...you have to go somewhere else first." department... Power is always calculated [[I'm sure this'll bring on the flame war, but understand what I say first, then decide if you want to get into that war]]

H O W E V E R...

If you figure out what the two powers are that were 3 dB apart (by whatever means you desire) you WILL see that they are in a ratio to 2 to 1.

Now a clincher... __IF__ you go back and look at the voltages (or currents) you measure at the 3dB point, you will see that they are __NOT__ in a ratio of 2 to 1! the ratio'll be 1.414 (sqr root 2).

This is because POWER is a second order quantity (in math terms) In Ham terms, POWER IS VOLTS TIMES AMPS. The product of two measurable quantities. IF the POWER is twice, then the voltage MUST be 1.414 times and the current MUST be 1.414 times... Then 1.414 X 1.414 = 2 DONE!

Said another way, HALF POWER is 0.707 the Voltage (AND current) _not_ half.

[[P.S. Put 1.414 (or 0.707 into the volts/current equations]]

THEREFORE, IT _AIN'T_ "6 dB volts". If you like {and to hear old Alex spin], call it 3 dB Volts, 3 dB amps, __AND__ 3 dB POWER, though the addition of "volts" and "amps" is sort of wrong (at least possibly mis-leading) and the addition of "power" is un-necessary (remember the definition of dB?). 3dB is 3dB power ONLY! (but it is different ratios when looking at the power vs. the current or voltage)

Now to the point, your point. The 3 dB point on your circuit _IS_ the 3dB point in current, it _IS_ the 3dB point in voltage, AND it _is_ the 3 db point in Power. Did I already say that...? I could give a specific example, but rather than me working that hard, go back and measure (well, let Spice show you) your current AND voltage at your 3 dB points and you'll see that the formulas DO apply. They will be only 0.707 down, not 0.5.

Hope this helps. If it doesn't then perhaps one of the flame responses will help you understand better. Good luck.

73, Steve, K9DCI

Half _voltage_ is 6 dB!

Bill,

Short answer.

I've often speculated about the answer to this same question and what I figured, is correct. Here's the mental model I use.

Quick look at Cecil's references shows that the voltage balun has an output center tap that is referenced (connected) to the coax input ground (shield). Thus making the two outputs balanced, voltage-wise in reference to the coax shield. a.k.a. a center tapped secondary, so-to-speak, which is referenced to "ground" thus making the two sides equal in voltage (peak).

Looking at http://www.eznec.com/Amateur/Articles/Baluns.pdf
Figure A3-3, note that there is NO connection between primary and secondary, so the voltage can do anything it wants, but the current at both ends of the secondary will be equal. Note that there are other ways to get this result where the primary and secondary (or the two windings) _ARE_ connected in some way. However, this is an easy way to see the intended difference.

OK, but that tickly feeling consists of many spikey pulses, and from Fourier, pulses consist of a whole series of higher order frequencies. However, this could be relevant, some scientist in Florida studying lightning has theorized that the strike is instigated by cosmic radiation, more specifically gamma ray bursts from blackholes. It kind of makes sense because if the CR creates an ionization trail in the atmosphere, this is a good initial conductive channel for the cloud's potential to drive a current into a suitable ground point. Awesome.

A*s*i*m*o*v

You need to do lots more reading in the right places. While possible for Gamma ionization (If it actually does ionize air) to help in some cases, the local field is many orders of magnitude higher than that required to break down the air in the first place without any help from the cosmos.

I think it opens up a new alternative to the lightning rod. Might some
form of radiation shielding be just as effective instead? If there are
no air ionization paths of cosmic origin under the shield then the
lightning has no place to start? Six inches of lead over the antenna
tower doesn't seem right though... perhaps some type of plastic
umbrella? Does anyone know if mountain top radar domes are hit less
often than other aerials?

A*s*i*m*o*v

... Forcast for tonight: Dark.

"...alternative to the lightning rod. ..."
Their purpose it to bleed off the charge so it can't develop to the point
where the leaders can start and prevent the strike. You need to get the
charge out of there, not let it continue to build until it finds another
path it can breach. Charge concentrates at a point and low level ionization
bleeds off the charge "safely".

You put large round balls on static generators so that you DO allow the
charge to build up and not bleed off.

The number we used in tubes was 10,000 V per inch. Unless my math is off,
this is only around 400kV/meter. Besides, what about the local field
strength, like at the tip of the lightning rod? Can there be a cloud effect
that somehow concentrates charge and gets the corona started for the
leaders?

Gene Fuller wrote:
'the unsolved mystery with lightning generation is how it can happen at all."

True. Distribution of the charges involved depends on temperatures, air currents, etc. For a given quantity of charge (Q), it equals the capacitance between the regions which hold it times the voltage between the regions. Q=CE.

If you increase the distance between the regions it brings the capacitance down, so the voltage must rise.

Natural forces may be adding to the total charge too.

You don`t need enough voltage to leap across a giant chasm to initiate lightning. You just have to start ionization when conditions are right and it will sustain itself.

Air consists of gas molecules which mostly have no net charge in their normal states. One of these molecules may be struck by an electron, dislodging one of its atom`s orbital electrons, and leaving it with a net positive charge. This process may continue, giving an ionized area which is conductive. This is likely at higher altitudes due to reduced atmospheric pressure. At sea level, normal pressure is 760 mm of mercury, but at 19 miles high, the pressure is only 1% of that at sea level. At rarified pressure, gas easily becomes ionized. Neon is under only about 12 mm of mercury pressure in the glass tubes of a neon sign and conducts readily.

The ionosphere is composed of ionized layers high in the earth`s atmosphere. Gas and ionization are mobile. A large voltage gradient produces ionization.

Working in a high-power shortwave broadcasting plant, I`ve seen ionized plumes on transmission lines. They don`t usually strike across the wires. They just follow the hot air they make, flaming upward.

Lightning is discharging some large capacitance which seems to produce its destination. A combination of forces directs its path.

Best regards, Richard Harrison, KB5WZI

Well, it is the angle at which the peak of the RF takes off.
If one understands what it means, it is a useful concept.

> And it seems that a lot of people get really hung up on that,
> thinking that there is some kind of blob of RF that leaves the antenna

Like any other concept, the user needs to understand the
definition. If the TOA of a ground plane antenna is 7 degrees,
that bodes well for DX, not well for local stuff.

For instance, the take-off-angle for a low dipole is 90
degrees, i.e. straight up. Good for NVIS, terrible for DX.

How about this?

Given:
P1 = V1^2/Z0, P2 = V2^2/Z0

P1/P2 = (V1/V2)^2

log(P1/P2) = 2*log(V1/V2)

10 log(P1/P2) = 20 log(V1/V2)

Sometimes an equation is worth a thousand words. :-)

Hi Matt,

The question?

"What is 6 times 7?"

Any question is certainly not on your horizon for discussion. Its
nebulous generality is not an invitation to discuss, it is a prelude
to a projected negative assertion made in terms of frustration.

If you are not hindered, you could have been more explicit. This
should be quite apparent.

The question, quoted from the book, is "What do you get when you
multiply six by nine?". And the answer is still 42. Which is obvious.

From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <11jrte940qbbf67@corp.supernews.com>
Source record: 69657

I second what Irv (VE6BP) has suggested. The modeling that I have done of small loops (just plain loops, no magnetic materials involved) placed horizontally (above earth) suggest the same pattern in all directions with a significant dip towards the zenith - just what one's receiver likes in order to receive signals from far away.

there actually is a clear air current that flows all the time, you can
actually draw power from it with a relatively small 'antenna'. in
fact,
many years ago one of the 'popular' magazines published plans for a
motor
that ran off the clear air electric field, you just had to be sure to
>disconnect it before a thunderstorm came through.

Has nothing to do with cosmic radiation, black holes, etc..
If that were the case, you would have near constant lightning,
in all kinds of weather. I have no doubt that lightning effects
the ultra high altitudes with the jet and sprites, etc. But I think
it starts from the strike itself, and effects upwards as some kind
of large recharge/discharge mechanism. But thats just my guess.
I really haven't looked into that much. How this guy thinks cosmic
radiation is the key, I dunno... Hummm... Is he a doktor with letters

after his name? He's not working off a government grant is he?
Inquiring minds wanna know...

Lee,

Using the loop indoors, at ground-floor level, at 20MHz, on a groundwave path, is not inconsistent with what you get. Get it high-up, outdoors, and it will make a big difference.

The capacitor is made from a length of coax. I wonder how long it is and how it is located relative to the loop? Wherever it is, being unbalanced coax it will unbalance the loop.

But what worries me, the very thin coaxial inner conductor is in series with the main loop conductor. It may have a loss resistance several times greater than the large diameter main loop. You could be losing a lot of decibels.

Reg, G4FGQ.

Hi Dave,

I saw something like this suggested in Popular Electronics in the 60s, but living in Colorado where the nearby strikes were like bullwhip snaps, I chose to pass this by.

Some years later, when I was called in to do another design for the Black Box upgrade for newer 747s, I ran across an article of interest.

This came from The American Institute of Aeronautics and Astronautics, November 1972 and was titled "Introducing Electrostatic Autopilots," Maynard L. Hill, John Hopkins APL.

The point of the article was to build a servo loop to control the level flying of model airplanes automatically. The sensors located at the wingtips measured the potential gradient that exists from earth to sky. When the wingtips banked, the gradient would present a counter potential to the control surfaces to force the airplane back into level flight. It was quite effective for an otherwise difficult task that to that point proved to be intractable.

Aside from the application, the science presented (and certainly proved by example) described this current you speak of as being part of a world wide current circulation by which lightning strikes were the return path (and seriously far greater in amplitude by the accumulation of charge).

"The air-Earth conduction current typically measures about
2.5ï¿½10^-12 Ampere/Mï¿½ ...
"... Relatively few persons realize that when a person
stands in an open field on a clear day, his head has a
potential approximately 300V more positive than his feet..."

By my reckoning from notes I made back then, the total current flow is 1800A over the area of the entire earth to build a potential of 350000V at an altitude of 50KM (the gradient is quite shifted at roughly above 2500 meters). This upward current flow is borne by dust and water vapor on thermal currents of air. This data was taken from measurements performed in 1953.

"we can readily compute that a continuous 630MW flow of
direct current power maintains this potential difference.
If this DC generator suddenly failed, the capacitor would
discharge completely in about 1/2 hour."

==========
Lee,

If you cut the length of coax into, say, 7 equal lengths and connected
them in parallel you will have a capacitor of the same value but with
a loss resistance only 1/7th of the single length.

More compact too. 6 fit very nicely round 1. Bundle them up in a
plastic bag to keep off the rain.

There is a listed formula for determining BW given wavelength/wire diameter ratio. There is also a description of the antenna's efficiency given that sam ration (btw, when said ratio starts to approach 1:1, the antenna ceases to be efficient at all and and other equally wierd effects begin to happen).

>
> I have a program, DIPCAGE2, which calculates the increase in bandwith
> due to increase in dipole diameter which demonstrates this
> disappointing point.

a program cannot begin to handle all the variables involved in how an antenna functions IRL. it can approximate those functions only under extremely controlled conditions (which do not happen in real life either). all a program is good for is getting you close and then you adjust the antenna physically to tune it.

SN> something. I see no pulses to talk about.

Have you ever seen an image captured with Kirlian Photography?
This is a process where corona discharge is photographed onto a film.
There was a lot of mumbo jumbo around this effect but it is quite
interesting as it gives a great insight into how charges arrange
themselves around an object and their behaviour, more so if observed
using a live action camera instead of a still. The corona discharge is
a dynamic event not simply DC. Just observe any high voltage
discharge, it never takes exactly the same path. Even a rectifier
diode never has exactly the same forward voltage when a constant
AC sinewave current is applied. No one is quite sure why either.

Anyway, the gamma ray burst theory is not mine but that of some head
of department professor big wig guy. So why should I disbelieve a phd
who actually writes this hypothesis up in a published paper? By
comparison, those denigrating the theory without much basis don't
impress a lot. They should "stop making their political allegiances
take a priority over expertise". And that is my new catch phrase for
the month.

Another guy (in Norway?) also claims that cosmic rays are responsible
for creating clouds and that the amount of cloud cover is linked to
the solar cycle. Apparently when the Sun cycle is in a minimum period
the solar wind lessens and allows more intergalactic cosmic rays to
reach the Earth. These cosmic rays promote nucleation of water vapour
in the atmosphere, thus creating more cloud cover and the Earth cools
as more sunlight is reflected. In a time of maximum the solar wind
increases and less cosmic rays reach the Earth, resulting in less
cloud cover and the Earth heats up more from the increased sunlight
reaching the ground.

I doubt that you know at least as much as I do, because you would realize
that your posts are completely off-topic for all of the groups that you
insist on posting your religion/atheist arguments.
It may have kept to a single thread, but I would disagree with you about it
swamping the newsgroups, since it your posts are almost two to three times
the on-topic posts for these newsgroups.
I don't understand the point that you didn't start the thread, but that you
are still posting to it. If someone else starts a fight and you just keep
hitting back, does that mean you aren't fighting? Now, I understand your
ignorance and why your arguments are all skewed.
Take your discussion to e-mail. This thread started on-topic, but people
like you, who can't follow rules, have denigrated it to an off-topic
discussion.

>
lightning doesn't prefer to hit the rod. the rod reaches out to the stepped
leader before other more blunt or lower objects around it. in the most
common case a large channel of charge is stepping down from the cloud in
50-100m steps. this charge is normally negative and attracts positive
charge to the ground and objects under it. as the downward moving leader
gets closer to the ground the positive charges build up on objects until the
field is high enough to start upward moving streamers, this is the corona or
st. elmo's fire or what makes your hair stand on end. these streamers are
all attracted to the downward leader and the first one to reach it completes
the circuit and triggers what you see as the lightning stroke by providing
that final ionized path to the large pool of positive charge on the ground.
higher objects of course have a head start in reaching the leader, and
pointy objects have higher field gradients which let them start streamers
sooner, so high pointy objects end up with a better chance of triggering the
lightning to hit them.

The rod is salient.

It`s the voltage gradient, which is not a uniform function of position or altirude, but is greater at sharp edges and points. These initiate ionozarion which precipitates lightning.

Dear Lee (G6ZSG):
Please do note that I was commenting on a receiving antenna, which is in need of an antenna mounted amplifier. The amplifier does not have hard-to-accomplish requirements for gain (20 db is good) or for input impedance. However, the amplifier does need to have very high IM performance and at least a high-pass filter to reject signals from the AM broadcast band.

Using a small, horizontal loop antenna as a transmitting antenna can be done. As you are finding out, coupling power into the loop is a challenge.

Good luck. 73 Mac N8TT

The intermod performance of a receiving pre-amplifier is of no
consequence with a magloop.

The Q and selectivity (of the order of 1000) of the loop at the wanted
frequency easily reject local high-power MF broadcast frequencies.

On 160m, It's difficult to hear any stations only 3 kHz away from the
wanted frequency.

Reg.

Hi Reg....

I took my little 1 meter dia (10 ft circ) loop outside lunchtime and mounted it verticaly 2ft off the lawn and tested it, not expecting anything special and found that comparing it to the G5RV that there was no noticable difference between the two!!...my friend and i switched out our preamps and attenuator in.

I even turned the loop face on and edge on with a change of 2-3 S points.. So, needless to say, i am rather impressed with the performance and bandwidth of 2:1 SWR about 180k.....so much so that i am thinking seriously of going for a 20 ft circumference or larger for 80 and 40 metres....

Regards.

Lee....G6ZSG.....Well impressed!!! :-)

You probably call the police a nazi, too, when they pull you over for speeding. How come everyone believes that they don't need to follow the rules and that when they have it pointed out to them that they are outside the rules, they are being "picked on." Is that what you were in school?

You don't need to be a physicist to do it.
Many Hams (without degrees in physics) do it routinely, and what's more,
they don't merely "detect" the reflected radio waves, they actually achieve
useful communication with them.

Dear Reg (G4FGQ):

I note with interest that your note was written in the early afternoon.

The subject of my communication is: small (much smaller than a wavelength) - non-resonant (input impedance almost entirely inductive if one looks into a single opening in the loop) - horizontal - loop antenna (no substances with significant magnetic properties are in the vicinity of the loop antenna) - used to receive incident EM waves (which have both E and H components). SNRHL receiving antennas

I do not know the definition of a "magloop." Apparently, such a beastie comprises a resonant loop antenna.

No knowledgeable person would disagree that a single tuned network with a Q of 1000 is "narrow."

My interest in SNRHL receiving antennas comes from an interest in practical HF receiving antennas that are resistive to types of noise that appear only to be present at isolated, open, rural, otherwise-low-noise sites. The noise involved does not occur in urban areas or even rural sites with many trees.

Consider some of the excellent wine from Michigan this evening. This state, with a coastline almost the same length as that of the island of Great Britain, produces some excellent products for your enjoyment.

Hello Lee,

Thanks for letting me know that by giving your magloop half-a-chance it performs according to expectations.

You have also demonstrated that the G5RV is not so hot as it is made out to be by salesmen and they who have never tried anything else.

No disrespect intended to G5RV himself, now deceased, who claimed only that it had a nice radiation pattern on 14.15 MHz which enabled him to work both Europe and North America from South America without having to climb ladders and change anything.

The magloop is by far the most efficient of all the antennas of roughly the same physical size. Both theoretically and in practice. It will do even better if you can get it well above ground in the vertical plane.

In the horizontal plane it works best at the higher heights, above surrounding obstructions like buildings. But in such surroundings there is room to erect full-size dipoles anyway, which will obviously do better still.

The main disadvantage on the 160 and 80 meter bands is the size, physical and capacitance-wise, of the variable tuning capacitor. You need a vaccuum capacitor of about 1000 pF max. By correct choice of loop dimensions and minimum capacitor setting the 40 meter band can also be covered. On 40 meters a small magloop can be highly efficient. Investigate using program MAGLOOP4.

Are you using the small internal coupling loop, about 1/5 diameter of main loop, to match to a 50-ohm feedline? This is the best and most simple way to go,

A different ratio small loop diameter is needed for other feedline impedances. The circuit behaves as if the turns ratio on a transformer is being changed.

Let us know how your experiments proceed.

Reg, G4FGQ.

> comprises a resonant loop antenna.

==========
"Magloop" describes a small, single-turn, thick conductor, usually made from copper water pipe, circular, hexagonal or square in shape, loop. The two ends of the loop are connected together via a variable capacitor. The capacitor tunes the inductance of the loop to a resonant frequency at which everything happens.

The term "magnetic" arises because the near-field of a transmitting loop is mainly magnetic as distinct from the electric field. On receive it is more sensitive the magnetic field than the electric field.

==========
The noise in rural, open, oceanic areas is just the same sort as in built-up, residential, city and industrial areas. It is all random but there is just a lot less of it.

An antenna of any sort is just as sensitive to noise as it is to signals provided both noise and signals are coming from the same direction and elevation.

Everybody has heard of the State of Michigan with its capital city of Detroit. I have always thought of it as an industrial state similar to my own area of the city of Birmingham and the surrounding Black Country of England. It is the manufacuring areas which produce the REAL wealth of this World of ours. Not forgetting the farmers.

Never having had the opportunity to visit Michigan it has not occurred to me that the land could also grow grapes and produce wine. (Actually, we do produce respectable wine here in cool-climate industrial England. But not much of it.)

It is now 20.00 hrs and too late to go shopping at my local super-market. Nevertherless, at my next visit I shall keep my eyes open for "Michigan" on the wine bottle labels.

Reg, G4FGQ.

Ahh Pat, so you are engaging in the ever clever tactic of replying to posts without adding anything to them.

Which indicates to me that you are more interested in getting rid of postings that irritate you, as opposed to any real desire to keep the newsgroup on topic.

Your tactic is seen on the bands where people record and play back other hams transmissions. I guess it is a particularly unimaginative form of Jamming.

Are you a Jammer, Pat?

Hi Mike,

If I recall correctly, the forebears of the untelligent design crowd,
during the scopes monkey trial, attempted to mandate that pi was equal
to 22/7ths. However, I don't see where faith attaches to 22 and 7 was
always a cabalistic device of the middle ages.

Close enough for as many as 3 would be.

I would hate to drive on their 13/14/15 inch tires tho'. ;-)

Hi Lee,

I'm a little confused about the bandwidth that you're getting. Maybe it can be attributed to losses which widen the SWR bandwidth. That's not necessarily a bad thing. I have used an AEA IsoLoop antenna that is about the same size as your loop antenna but has a low loss butterfly capacitor for tuning 10-30 MHz. On 20 meters the bandwidth is only about 20 or 30KHz(can't remember exactly since I haven't used it for a couple of years). It works great if you park yourself on a frequency but it is a pain to use for hunt and pounce.

Besides the null using vertical polarization, is it possible that for your local friend you may have been cross-polarized. Usually direct wave cross-polarization is on the order 20db which accounts for the 2 to 3 S units of change from vertical to horizontal.

Have fun with your new toy!

I have a copy of an article that gives a good overview of the cosmic ray hypothesis. It appeared in the May 2005 issue of Physics Today.

The authors are:

Alexander V. Gurevich and Kirill P. Zybin.

Their affiliation is described as:

A.V. Gurevich is the leader and K. P. Zybin is a research scientist in the I. E. Tamm theoretical department at the P. N. Lebedev Physical Institute of the Russian Academy of Sciences in Moscow.

I can e-mail a PDF copy (about 250 kB) of the article to anyone who wants one. Send me a message by correcting the rather obvious munge in my e-mail address.

As I noted previously, I do not have any particular expertise or vested interest in this cosmic theory, but I do find it interesting.

73,
Gene

Reg, I grew up in Michigan, and spend 6 mo a year here, the other 6 in Florida.
In all the time I've spent in Michigan I wasn't aware that Detroit is the
Capitol. When was it moved from Lansing? Perhaps Mac can help you out in this
dilemma you're creating.

Indeed. But it is such a misleading term. It gets people to believe that an antenna which is very inefficient, yet have a low "takeoff angle" is somehow superior to an antenna that may have a higher TOA, but may have more overall "oomph" at the same angle as the lower TOA antenna.

No argument there.

> degrees, i.e. straight up. Good for NVIS, terrible for DX.

I kinda disagree. Unless that antenna has a teardrop shape pattern, it might still not be too awful bad for DX. Of course it won't be as good as an antenna that has good output, with most of it at a lower angle.

Of course, I'm a bit of a dilletente, and could be making a fool of myself here! 8^)

> The term "magnetic" arises because the near-field of a transmitting
> loop is mainly magnetic as distinct from the electric field. On
> receive it is more sensitive the magnetic field than the electric
> field.

--- I am obliged to you for providing a definition of "magloop." The critical element of the definition seems to be that a magloop is a loop that is resonated by a reactance.
--- I am puzzled by your observation with respect to the term "magnetic" in conjunction with a loop antenna (presumably a loop antenna, whether or not a magloop). You appear to be saying that a loop antenna is more sensitive to the H field than to the E field of an incident EM field.
--- Relative to you, I have only been dealing with antennas a short 50 years. However, in that time, I have only encountered antennas that extract a signal from an EM field where the ratio of E to H is well established. My graduate professor, who recently passed away and who wrote The Book on antennas, never mentioned antennas that inherently were sensitive to one component of the incident EM wave.
--- Perhaps what you were saying is that one can predict the polarization of an EM wave launched from a loop antenna from knowing its geometry and the observer's orientation with respect to the geometry. This is also true for a doublet and a number of other antennas.

>
> ====================================
> The noise in rural, open, oceanic areas is just the same sort as in
> built-up, residential, city and industrial areas. It is all random but

> there is just a lot less of it.

--- I do not have the verbal skill of Richard Clark, who could find an elegant way to say what needs to be said. Dear Reg, you are wrong. You are wrong because your long and extensive carrier has not placed you in the sites described. Had you spent time out in the sticks, bare of same, you would have encountered the discharging of charged particles into the antenna you were using (or discharging into nearby conductors) producing a prodigious amount of excess noise. The particles are sometimes dust particles, sometimes water droplets, and sometime snow. By far, the greatest limitation on the performance of an HF receiving site in rural, open country is the sudden appearance of this noise. Even at VHF, it is sometimes a limiting factor. State Police posts in Michigan have sometimes not been able to communicate with 100 watt mobiles that were less than 300 meters away because of this noise appearing in a snow storm. (Movement to much higher frequencies and other strategies have alleviated their problem.)
--- My experience does not extend to extensive receiving sites out to sea. They might, it they exist at all, not encounter the excess noise. It is also clear that high air humidity may serve to reduce the excess noise.
--- Please add to your vast reservoir of knowledge something new.

> REAL wealth of this World of ours. Not forgetting the farmers.

--- Well said! Michigan has had the most productive industry in the world. It also has some of the most productive agricultural land - especially for being in the north. However, Michigan (and others) are going through a major change. The advent of fast, inexpensive communication and transportation have seen the movement of vast numbers of manufacturing jobs to areas where wages are low. Many square miles of factories have been pulled-down to bare ground. (Taxes are thus reduced - often next to impossible to sell the land because of unknown pollutants from 90 or more of industrial use.) Ascendant in Michigan are jobs that produce intellectual property, that are involved with higher education, and that are involved with medicine including research. The new worker is different.

--- While Detroit is still the largest city, the capital is in Lansing.
>
> Never having had the opportunity to visit Michigan it has not occurred

Hi Mike,

You make a valid point, but it bucks the trend of braggin' rights.

For instance, one of the loss leaders in fractal design also has
better launch characteristics at low angles because it uses ground as
a director (and not simply straight up). Consider:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm

This page contains the design ready to download - no threat of suit in
over 4 years - and it was no threat before then either. Also included
is my own non-fractal (at least in this iteration :-) version. It
also performs just as well, if not better (hard to say that without
biting my tongue however).

73's
Richard Clark, KB7QHC

p.s. qsl.net served up my page so fast, I thought I hit the cache! My
pages are so heavily laden with data, they are not simple downloads.

My recommendation is to hold off on the MFJ 'tuner' and first put up the antenna and see how it plays. As to where to buy; Lowe's, Home Depot or whatever similar type place will be your best bet for the wire - suggest #12 or #14 stranded just as you would use to wire your house. Insulators can be made from wood, use some 3/4 square cut 3 - 5 inches long with a hole drilled in each end then seal it with several coats of varnish. For more info this article is highly recommended:
http://www.anarc.org/naswa/badx/antennas/low-noise_antenna.html

Good Luck,
Howard

Meteor scatter is pretty common among us folks that get our butts out of
the HF ghetto upon occasion. That, plus the occasional second hop on E,
AuE, TE, or F (when in season) can provide a nice DX surprise.

The controls have already been put in place. The idea of posting on-topic
is nothing new and most people find a way to keep themselves within those
boundaries.
I would imagine that the band plans for the amateur radio frequencies are
only a "guide" for you, too, and that you feel that you can transmit in any
mode and on any band that you feel fit. Right?

It is supposed to work on 2-40 meters, and is located on page 83 of
HRO's (hamradio.com) online PDF catalog.

Pat, usenet has no controls "put in place" (except on moderated newsgroups).
Each newsgroup is commissioned for a stated purpose and should generally be
followed, but sometimes the exhuberance of the moment causes us to stray off
into other areas. S#!t happens!

> I would imagine that the band plans for the amateur radio frequencies are only
> a "guide" for you, too, and that you feel that you can transmit in any mode
> and on any band that you feel fit. Right?

Bandplans are voluntary "guides", and generally make good sense. Times happen,
however, when there are good reasons to deviate from a particualr bandplan. So
long as the mode/band is FCC-legal and I have a personally-acceptable reason,
you're right --- I >>do<< feel that I can take a one-time exception to the
bandplan guidelines.

I agree that it would have been nice if TOA had not been defined that
way. What I always attempt to do is state a gain to go with the TOA.

Buther,
I'm going to refer you to another website that has further explained
it and offers some illustrations - a picture is worth.......

Yes, it's a bit of laziness on my part and also an admission that I'm
not so hot at writing instructions. A few tips though:
1) Insulators; wire antenna attached to one hole, rope to the other -
the rope ties off to a support such as a mast, tree or house.
2) Lead in wire/transmission line; the wire can come directly to the
house but can pick up lots of noise, using coaxial cable (and a
suitable ground) can help reduce this - attach the center conductor to
the antenna and the shield (braided wire just under the plastic
jacket) to ground. if for listening only go ahead and use 75 ohm
cable as you would buy for your cable or satellite TV system.
3) Ground; a metal rod, typically 8 feet long, driven into the ground;
you can use the ground rod for your home electrical.
4) Keep your antenna as far from power lines as you can and
perpendicular to the power lines (if nearby) can help to reduce noise
vs parallel to them.

Here's the site promised: http://www.kc7nod.20m.com/random_wire.htm
Thanks to KC7NOD for taking the time to put this info on his site.
Also, don't forget that Google is your friend, type in 'random wire
antenna' and you will receive a wealth of other info.

Howard

<snip

Well, for me Reg, the halfsize G5RV was the only multi band antenna that i could squeeze into my garden...and the bandwidth of the loading coils for 80 is below my expectations..... that`s apart from the fact the loading coils knocked out 40...ho-hum time for a better antenna that isn`t an eyesore...and works better as a bonus.....
On VHF, beams and quadloops are no problem for 6m even, but HF is a whole new ballgame....had i the space, i would continue with quadloops for HF....but!!!......(shakes head).

> Are you using the small internal coupling loop, about 1/5 diameter of
> main loop, to match to a 50-ohm feedline? This is the best and most
> simple way to go,

No. i`m using a `gamma` match, if you can call it that....the matching loop comes next.
Wonder if a coaxial gamma match would work as i`m a staunch believer....(could put that principle to use for the capacitor tuning instead of a butterfly variable......)
Can`t get on with other types of loading, too fiddly!.

Regards....

David

1583. Help with Sleeve Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-02 07:16:01 UTC
From: David <groups@orbitcoms.com>
Message-ID: <ROL%e.4884$U51.366@news-server.bigpond.net.au>
Source record: 69580

I am a little confused with calculation of appropriate length of metal tubing used in a sleeve antenna design (the 1/4 wave section).

I understand that as RF travels through various mediums, Velocity of the wave slows down relative to Er of the material. So for coax the wavelength would be say 0.66 Lambda.

With the tubing over a coaxial cable though it seems there is Vp related to the dielectric formed between the sleeve and the outer sheath of the coax cable but also the Metal has an Er value.

1. Do you need to count for both these when calculate how the tube should be.
2. Is there relationship that needs to be considered between sleeve length and distance between sleeve and coax (ie. If the sleeve is made larger diameter does it effect the length required for the tube or is this still defined strictly by Er) also, Does the diameter of the tube effect the impedance ?

The specific example is RG174 Coax cable vertical dipole. The top radiating element is 1/4 long. At the bottom of this element is a length of RG174 Coax. 1/4 wave length of this coax has a 5/32 Brass sleeve. The sleeve is soldered to the RG174 coax at the point where the coax meets the top 1/4 wave element.
I need to understand what needs to be used to calculate the length of Brass tubing sleeve given the tubing diameter is 5/32 and besides air, the outer sheath of the RG174 is also between the sleeve and Earth braid. Is the diameter of the tubing critical (will it impact adversely on SWR looking into this antenna).

The final point would be if I place some ferrite rings across the coax below the sleeve, will this improve SWR ?

Thanks

Regards

David

Hi David,

The Er of the metal is not something that comes quickly to mind
(especially this late at night). Besides, it sounds like what you are
describing is the radial component which would be fantastically small
(many decimal places, not simply tens of percent).

It also seems like your application is for UHF (you need to be more
specific). This makes such "calculations" little better than SWAGs.
It doesn't take much to be way off. What is even more confounding is
your problem contains a hidden trap.

The sleeve of brass that drops below the feed point is embracing the
jacket of the RG174. THIS constitutes the dielectric constant of
interest and is a material that is different from the insulator of the
inner line. Even more, and as you note above, there is some air mixed
in to really gum up the back of the napkin calculations. This is the
G of the SWAG.

Worst yet, some jacket material is actually quite lossy, or so it has
been reported - another G of the SWAG.

All-in-all, what you need to do is build one and measure it. No doubt
that will lead to another trail of tears. On the other hand, there is
nothing so stimulating to learning than pain. Most of my best
subjects centered on projects I thoroughly screwed up.

As the saying goes:
"If you haven't failed, you aren't trying hard enough."

Walt,

We are all sentimentally attached to the area where we were born. I find it intriguing you were brought up in the same sort of industrial region as I was dragged up in. There are a few descriptive paragraphs in "A bit about Reg" in my website.

Please forgive me for assuming the largest city of Detroit to be the political capital of Michigan when it is actually Lansing.

Again there is a similarity. The political capital of Warwickshire is not the largest city of Birmingham but the small ancient town of Warwick with its castle, not far from Shakespeare's Stratford-upon-Avon.

Is Michigan named after an Indian tribe?

Reg.

What is a "'loaded' half size G5RV"?

Googling for info, I see a few suppliers with loading coils for a half
size G5RV (complete with instructions), but could not find an article
with physical dimensions and loading coil characteristics.

Is this a "proprietary" antenna, not open to independent analysis.

In its "normal" mode, a (full size) G5RV has feed system losses on
160m like cricket scores. Intuition suggests that a half-size G5RV
(where everything is scaled to 50%) will have similarly appalling
performance on 80m.

Has anyone seen details of the loading coils for this "loaded
half-sized G5RV', or models of its performance?

Owen

Richard,

Thanks for the feedback. No problem with the failing issue, plenty of
that going on.

The way I see it though is that if I can add some knowledge to my
experimentation then at least I can "play" with some hope of moving to a
solution in the right direction.

Dear J.

Birmingham and the Black Country has suffered a similar fate. Once upon a time EVERYTHING was made in Birmingham. I began work at the age of 14 in an electric motor factory. (I've never met a university professor.) Factories have now been converted to museums as an adjunct to the tourist trade.

Only this very week, the last of the once-upon-a-time many Black Country iron foundries poured the last few tons of molten iron from its furnaces. Sadly, three months back the last of the 100-year old motor factories, which started with bicycles, closed its gates rendering 15,000 people redundent. Motor production is to continue in China. Not that I have anything against the enterprising, hard-working Chinese who bought the factory complete with the intellectual property. Good luck to 'em.

The rot set in with Lady Maggie Thatcher who favoured the so-called 'service industries'. Now we have Blair who's selling off the Health Service and has loaned the British Army, free of charge, to the Americans. But we can't get rid of him until Bush has gone.

Now back to, the always with us, SWR. ;o)

Yours, Reg.

The velocity factor of any conductor, including tubes, depends only on what surrounds it.

If the surroundings are air, which is mainly oxygen and nitrogen, then the VF = 1.00, equivalent, in metric units, to a velocity of 300 metres per micro-second. Or in ancient, old-fashioned units, it is the far-less-convenient 669600000 miles per hour, give or take a few 100,000 miles. Who cares?

Howard:

I somehow "dreamed" of being able to hide this random wire in my house
and tune it up, but that is looking more improbable by the minute. I
live in a town home and have no yard. Things don't look good, but I
have an excellent idea of how this all works. I appreciate your help,
Howard, and thanks for the detailed explanations.

OK, so the electrical wavelength of the tube will only be effected by
the dielectric material and it does not make any difference how large
the gap is between the Sleeve and the Coax ?

The frequency of operation is 920 MHz.

Do you happen to know what the covering is made of on the outer sheath
of RG174 ? The cable I have has a stranded inner core and seems to have
a PFTE dielectric. (Doesn't melt at all when soldering so I assume this
is what it is).

25 years ago, I had one in a 3rd story apartment. I mounted the whip in a window, about 20 feet up. It worked reasonably well. I was able to tune it up on all bands, including 40 meters. The key is to adjust the length of the counterpoise wire for each frequency you tune up -- I had the wire on a metal spool, and rolled or unrolled the wire till I had low SWR. That wire is hot with RF, so I had a hot wire running across the apartment rug, and you have to watch that. Since you're in a townhouse, you'll be able to ground your station, which I was not able to do in the apartment, so you'll be ahead on that count.

For limited space, it's a pretty neat setup, and you can make contacts with it; not as well as with a dipole outdoors, but it works.

Get your tuner, get a 500 foot roll of #14 insulated wire from Lowes
or Home Depot (about $30), order a copy of the ARRL Antenna Book from
their web site for the particulars on random or long wires, and you'll
be all set.

Source record: 69592

I'm a bit confused over the construction of a vertical colinear.

The docs I've seen all are more or less the same, alternating half-wave sections of coax or hardline.
The thing that's bending my head, is that there's a velocity factor inside the coax, that presumably isn't there on the outside.
So, while a given section is a half wave on the outside, it's probably more like 3/4 wave inside.

My understanding is that we are trying to get to a series of dipoles all fed in phase, and yet this seems like it's not accomplishing that.

What am I missing?

1598. Need Suggestions for a Relay Source

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-02 16:14:32 UTC
From: Brian Kelly <kelly@dvol.com>
Message-ID: <1128269672.814425.42830@g14g2000cwa.googlegroups.com>
Source record: 69595

I'm looking for a source for small inexpensive 12VDC relays which are usable for cold-switching ~200W of RF at frequencies up to 30 Mhz. The relays would be used to remotely select several single-band antenna tuners and several end-fed vertical wire antennas strung up into some tall trees. The "tuners" would be link-coupled tapped parallel tank ciruits, one tuner per band.

There would be two relays needed per band, one to switch the 50 ohm coax from the shack to the specific tuner and the other at the output end of the tuner to select the particular wire. At the input ends of the tuners the RF voltage would be around 200V @ 2 amps. At the output ends of the tuners (depending on the feedpoint impedance) the RF voltage could go into the 2kV range at very low currents. So basically I need some sort of relays which can handle 2kV of HF RF at 2 amps. Single pole NO non-latching reed switches would do the job.

I know I can use surplus vacuum relays but at $35-40 a pop that ain't gonna happen.

Any and all suggestions will be appreciated.

David;

That's why they call it the ART of antenna design. First you make the
best mathematical calculations you can then you start cutting
wire/tubing. Make your lengths slightly longer than the math says then

prune the lengths until the antenna works the way you think it should.

There are so many variables in antennas that this is the only practical way to make a new one. Once you find your optimal lengths you can make more to the same specs. However remember that just like in housing antenna's depend on three things: location, location, location and have to be custom adjusted for each site.

From what I understand, the RF will be traveling on the outside of the
sleeve, and won't "see" the internals at all.
So, the sleeve ends up as a 1/4 wavelength stub.

Is the diameter of the tubing critical (will it impact adversely
>> on SWR looking into this antenna).

It shouldn't be

>> The final point would be if I place some ferrite rings across the coax
>> below the sleeve, will this improve SWR ?

Not if the sleeve is doing it's job.
The sleeve's open end should look like a short at the operating frequency,
and keep RF off the feedline.

I think it might have been Richard C. who nailed it that it makes for
better claims by manufacturers.

No, I only spent a couple of minutes looking. I thought it was interesting
that the shoe is now on the other foot, for you. Found your page
interesting, too.
However, I find it ironic that you call me a yankee. I have been trying to
shed the southerner image here with my friends and coworkers ever since I
moved up here from Myrtle Beach, after retiring from the Air Force. I grew
up in Beaufort, SC, near the Naval Hospital. Most people say that I still
have the accent.

If you wish to keep common mode off the feedline you will need to add
decoupling.

That's the old AEA ISO-Loop had that extra sleeve.

Brian

Have you considered building your own coax relays? It is fairly easy to
construct a SPST coax relay with glass enclosed tube shaped reed relays.
Their performance may be acceptable to you, maybe not. But I have built my
own coax relays from regular relays and have gotten adequate performance.

The wave energy travels alternately on the outside of the center
conductor and then on the inside of the braid or shielding. So both
see the same velocity factor. Does that make sense?

BB> Buther Boy

You can hide wire in the oddest places. For example there is a 40 foot
long clothesline outside in back of the house and it is made of steel.
Someone a little bit crafty might replace that line with copperclad
and nobody would be the wiser unless they looked a little closer.
Hidden in plain sight!

Hi Brian, the Omron LY series seem to handle 100w for me.
Perhaps you can contact Omron about their limits.

Hi dave

I dont think you are missing anything. The feed points of each of the
radiating elements need to be in phase if 'broadside pattern max' is
desired.

Do you intend to build an array, or just trying to understand them?

Jerry

Both. I have some FSJ1-50 that I got for the purpose.

The docs that I've seen are all pretty consistent on how it should be put together, but I just don't understand the workings of it.

IF the coax had a VF of 1.0, then it would make sense to me.

By coincidence, I was reading an electronics mag over breakfast today,
and saw this press release:

"Crydom has launched a high performance miniature reed relay boosting
carry currents by 33%. Fitting a full electrostatic copper screen that
completely enshrouds the relay coil, a reduction in power loss is
achieved. Lower loss means lower self heating – enabling an increase
in carry currents to an industry leading 4A RMS at 30MHz from the
miniature 30mm x 10mm package.

"The 6 Series is designed for next generation HF antenna couplers and
filter circuits where improved RF performance and higher packing
densities are required.

"The hermetically sealed high vacuum reed switch will isolate 3kV
minimum (DC or RF peak) making it suitable for a range of Test Equipment
and Electromedical applications where high voltage, high current pulses
are generated."

Without necessarily endorsing that particular product, there are a few
interesting points:

* Switching in HF antenna couplers and filters is now a recognized
market.

* Reed relays can handle this kind of service.

* Coupling into the coil can be a problem, which may suggest making your own. Crydom use a shielded coil, and an alternative idea ISTR is to wrap the glass relay tube in foil instead of the coil. (In both cases the shielding would need to be overlapping but non-shorting.) Which is the better would depend on the application, and how much shunt capacitance it can tolerate.

More details and a data sheet at:
http://www.crydom.co.uk/Webpages/archive-new_fully_screened_rf_relay.htm

Dave

Have you looked at the collinear antenna on the web written by "Brian Oblivious"? He cuts the coax into equal lengths 1/2 wave each. And that 1/2 wavelength accounts for the velocity of propagation inside the coax. So, each length is somewhat shorter than the free space halfwave It shows how he connected lengths of coax to make a collinear array. In my opinion, that would be a waste of that good coax you have.

I once manufactured a vertical collinear antenna that had only one feed point and the other collinear elements were passively connected when stacked below the "fed dipole".

Sometimes it is convenient to mount vertical half wave dipoles around a vertical supporting mast and have a "corporate feed harness" within the mast. That works well.

1621. Emergency Messaging And AM

rec.radio.amateur.antenna,rec.radio.amateur.misc,rec,radio.amateur.equipment

Novitiate here:

I am learning AM broadcast basics in particular the issues regarding the geo-targeted broadcasting of alert messages from moving vehicles. Would most appreciate any assistance.

Due to Katrina/Rita, the company I work for has been given the opportunity to demonstrate a messaging system that would reach out approximately 1 mile +/- in transmission deliverance. This would be an "overbroadcast" (my term) in that it would override local AM radio broadcasting to reach into cars, trucks etc. In particular, we are working with a stationary site (a chemical spill for instance) and an emergency vehicle that would move back and forth at and through the site, at up to 70 mph, broadcasting an alert, voice and tone message.

Reading about LPAM, this looks technically possible but one concern I have is antennae size. A fire truck, for instance, could have an antenna mounted on its front, and up to 4 feet over the top of its roof, so we might look at as much as 20 feet of length. I realize this places us over the 3 meter max so one of the ???? is whether LFAM is realistic.

Am I way off base here, can any antennae, fractal or other, or any AM antennae technology, be utilized to design an antenna and propagate this type of signal?

All comments appreciated.

The articles I have seen are 1/2 wave * the velocity factor.

Each one connecting center to shield.

I can't picture how the elements all end up resonant, and in phase.

Seems like one of those can't be true.

Why? It's nice rigid coax, and takes that sort of soldering well.

Dave

I didnt mean to imply that your good coax wouldnt work well. I (perhaps
wrongly) assumed that some garden variety coax might work OK for that
staggering of lengths of coax, inner conductor to outer conductor.

My web service thru Google, gets me that Brian Oblivious + Capt Kaboom
site on their 802.11 2.4 GHz antenna. They indicate that the "elements" are
1/2 wave long minus the Vp inside the coax. That will put the feed points
along that 'staggered' array, in phase.

You have probably already considered that there will be some beam squint
with this type of collinear. The "corporate fed" collinear will a
maintain a main beam broadside, even though sidelobes do increase with

bandwidth.

The things that pop into my mind are why AM rather than FM, which tends to
be more local, and do you intend to 'over-broadcast' only the local channels
(how many?) - I assume you intend to make the channel(s) selectable - or the
entire band to ensure you get everyone? Assuming that there is a commercial
AM broadcast station in the vicinity (what, 10 miles? 20 miles?) you are
probably going to be flat out getting a mobile rig to ride over it. How do
you intend to do this?

Cheers.

Ken

A disadvantage I see is that a waiver is going to be required in order not to violate FCC rules. In fact, in the state of Florida, interfering with broadcast stations is against state law, so another hurdle to be overcome. That being said, for this system to work, you have to blanket the entire AM and FM broadcast bands. Even doing so will leave out the motorists who use XM or Sirius, the Ipod listeners and those who are driving with their cellphones plugged into their ears.

1627. using 450 ohm twin lead to feed 43 ft multiband groundmounted vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-03 00:08:17 UTC
From: Denton <denton@oregontrail.net>
Message-ID: <11k0tjh6hr34l44@corp.supernews.com>
Source record: 69624

I have been tinkering with a 43 ft ground mounted vertical with an extensive buried radial field. With a 4 to 1 voltage balun at the base, I have a good swr match particurlarly on 20 meters, and the antenna radiates and recieves comparabily with my 10 horizontal cage doublet fed with open wire ladderline.
I recently replaced the coax that feeds the balun at the vertical's base with 450 ohm twin lead utilizing the same balun at the antennas feedpoint, and still get a decent signal report...again comparing to the big cage dipole. The twin lead is enclose within some left over grey plastic conduit if anything to keep it out of the weather and to keep it about 2 feet off of the ground, parallel to the ground.There is no evidence ot the plastic conduit detuning the twin lead.
Tuning via either a link coupled transmatch or a dentron super tuner plus, utilizing its internal balun is broad smooth and no evidence of rfi in the shack with the exception of 30 meters.
Wonder if anyone has tried this before and how did they like this feed arrangement.
Thanks in advance, de Denton WB7TDG

Hi Ari

I always wonder whether broadcast at the most common IF frequencies would be a viable alternative? (eg 455khz for AM) Legality issues aside of course... This would make frequency selection a little easier to engineer. You wouldnt have to divide your power budget into many operating frequencies as well. Problem is that you'd need a lot higher ERP especially since car mounted radios tend to be better shielded than portables. (You'll need to experiment some)

Since part of your engineering exercise will be to determine what ERP you want from the system you are proposing, the size of the antenna only needs to be considered in line with the transmitter output power. Obviously there will be a useful compromise somewhere that is cost effective. You might for example want a 100 watt TX for each frequency with a fairly lossy/terminated and loaded antenna. Your first port of call will be to determine what the likely highest strength of an AM/FM broadcast signal you will need to override, add maybe 20dB to that and work out your needed ERP. You will find lots of texts about the inefficiencies of MF antennas mounted on motor vehicles so that will give you some numbers to work with. Remember that making the antenna wideband will also introduce substantial loss. Note that you cant design the system to always work as you'll have situations where the radio stations transmitting antenna is right next to then freeqy where the event occurred! Decide on some statistical coverage percentage thing etc etc...

I worked for a concern in Sydney Australia that put in tunnel rebroadcast systems in the major underground roadworks in Sydney, Melbourne and Perth. Being in a tunnel of course there werent really any licensing issues. The system consisted of not only broadcast band (AM & FM) receivers but spot VHF/UHF FM receivers and transmitters for police, fire etc vehicles. Each broadcast frequency had its own transmitter. It was thought to be a better idea than using a wide band TX covering all frequencies. AM broadcast was coupled to a very long wire and the rest used a terminated leaky coax run.

And what makes you think anyone is going to be listening on AM. I
think the vast majority of radio listenings in urban areas listen to
FM except possibly for drive time shows, 24 hour news stations and the
comparatively few people enamored of talk or religious radio. FM of
course is subject to the capture effect wherein the strongest signal
prevails to the exclusion of others (at least that is the theory).

AM, particularly at night is subject to strong skywaves.

I think the problem here is not the technology, but a fundamental misconception of what it is you are trying to prove and who is likely to be your audience. At this point you do not need an engineer, you need a sociologist.

I agree Bob. "Tunnel Radio" systems have been around for over 20 years, and AFAIK all broadcast on dual IF frequencies covering both am and fm car radios. Here in Boston this type of system is in use in all our tunnels.

1631. Re: Help with Sleeve Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-03 02:02:13 UTC
From: David <groups@orbitcoms.com>
Message-ID: <Fi00f.5538$U51.2968@news-server.bigpond.net.au>
Source record: 69528

I am still confused on this one.
I see a 1/4 wave radiating element joined to another 1/4 wave radiating element that just happens to also act as a choke to reduce RF on the return braid of the RG174 coax.

The point where they meet is supposed to look like the centre of a 1/2 wave dipole so the impedance must be around the 72 Ohms

If the Sleeve is acting as a choke(Stub) then does it not need a second element as the return (ie is it not acting like a 1/4 length of coax where the tube is the outer braid and the RG174 cable running up the centre outer sheath is the dielectric and the outer braid of the RG174 becomes the inner conductor of the stub)?

If this is correct then the electrical length of the sleeve must be modified by the presence of the RG174 coax outer sheath. The sleeve is sort of performing a dual function.

As it is difficult to cut the tube once soldered in place, I will need to make heaps of these to get the length right. At least if I had a reasonable starting point it would minimize the number of iterations.

The other issue is that I read about cutting lengths for elements and not that even an element in free space is trimmed down by about 3% to account for some "end effect" ? Would this also apply to my sleeve ? If so, then the length may be difficult to get right because if I make allowance for the end effect then the choking effect of the sleeve will not work as well.

I do not want to reinvent the wheel here as these antennae are sold already being sold commercially and I am sure there are numerous people who have successfully made these. Therefore if I can learn from other people's mistakes and success, the starting point is much closer to the solution.

I have a practical application but want to understand also. The requirement is that I have a small antenna that can be built into the end of a RF connector and plug directly onto a radio modem operating in the 915MHz band. The power is 1 Watt max. The design needs to be repeatable and not require trimming at every location (being portable I have no control over where the unit is located), as there is no decent ground plane, I need a unit that does not require radials or large ground plane.
The low radiation angle and no requirement for large ground plane made the J-Pole look like a good contender but it was physically difficult to mount in this application.

After looking around and opening up some commercial units, I noted many used the Choke Sleeve, 1/2 wave dipole antenna.

This is why I am now wanting to understand how these work and have a good starting point for making them. The commercial units used molded construction that was difficult for me to emulate. I have started with RG174 Cable, 5/32 Brass tube all attached to SMA plug and used 1/4" nylon tubing as a radome. It goes together well and looks good but does not perform very well.

Thanks for any further info.

Hi David,

I think I pointed that out already. The effects of this jacket are
variable across many suggestions offered here over the years.

>As it is difficult to cut the tube once soldered in place, I will need
>to make heaps of these to get the length right. At least if I had a

Ah yes, the pain of it all. I mentioned that too. You may as well
grit your teeth and set to it, there is no shortcut to this all.

>The other issue is that I read about cutting lengths for elements and

You might want to work this backwards. That is start off with a
successful choke section of the sleeve. Let that dictate what follows
because its isolation will mediate what I describe. If you have any
experience with what is called an Offset Center Fed Dipole, you would
find that it offers a closer match to 50 Ohms. You are using the
dipole as a variable match by finding the 50 Ohm portion along its
full length. This means that the portion above the sleeve's
attachment to the drive point may not be the classic length (and
certainly not accounted by the 3% of the "end effect" - not even
close).

That is neither here nor there because at that point you will have
simultaneously achieved resonance, a match, and isolation; and yet by
no fixed formula pulled out of a hat, nor accredited by an institution
of higher learning.

And, by the way, it isn't going to pull together in the first pass. I
hope you have a stack of tubing, so put on a happy face and get down
to it.

How do you know? It might be doing the best job you could ask of any
design. Your statement requires FAR MORE qualification than a rather
subjective toss-off.

In other words:
1. To what parameters?
2. Compared to what?
3. By what measure?

Richard,

With regard to performance.

Doing an A/B comparison between the commercial antenna and my version. The range achieved by the commercial antenna was approximately 4 times the range of my version.
The range was determined by loss of using one end as a beacon and moving the test unit further away until it could no longer receive valid packets, then move in and out of range several times to confirm consistency. The same was done with my version.

Before the test, I monitored the return port on the directional coupler on a Spectrum analyzer while seeping frequency from the sig. gen and noted the SWR on the commercial unit was lower than my version. (Though the measurement was not calibrated I could see the SWR was better but did not determine how much).

Previously I designed a Microwave movement detector that operated at 1.2 GHz using Doppler principle. It used a microstrip tank circuit connected to a negative resistance oscillator. The design was published (RF Design magazine Dec 1986).
Though there were many technical issues regarding the oscillator (how to adjust impedance in the base for optimal negative resistance looking into emitter, effect of moving the antenna, ground plane under the antenna etc etc), others were able to make the design just as per my prototype and it worked. They could then proceed to"play" with the design to change its performance.

I really would have expected that a similar scenario would exist with antenna design (Someone has made one just like what I am wanting to make and is able to share with me the details on what they did that worked, then I would play with the design).

I am grateful for the many responses I have received from my postings to this group and am confident there is much good information in what I have received but mixed with people's actual experience is a bunch of theoretical information that makes it hard to pick out what is useful. (ie. some of the information has conflicted and left me not understanding what is actually happening here).

If someone has actually made these types of antennas and has some practical experience with them, that would be a fantastic starting point for me. (ie. Low power, UHF, portable).

Well, Ari, I can tell you this. People used to mock the fact that I had 7 antennas on my 1957 station wagon almost 50 years ago, but these days, the airwaves are so bereft of anything worth listening to, I never turn on a radio in the car. So, I will never hear your message no matter what you try.

Now, having said that, here is how the system design needs to be:
Since the frequency to which a target radio is tuned is an unknown, and since the input contains a good trap for the IF frequency, your transmitter needs to radiate about 2 KW ERP at each of three frequencies in the broadcast band separated by 262 kHz and 455 kHz. This will mix in the front end and produce a useful IF. Same technique on FM using two frequencies 10.7 MHz apart.

Good luck on the AM. With expected antenna efficiencies at that wavelength of about 3%, you are going to need over 100 kW of RF and antenna components with equivalent power ratings.

Let us know how it works out. The place I used to work no bid this about 20 years ago due to these problems, and that was not the first time this crazy idea surfaced.

Hi David,

This suggests your problems are indeed very profound. A 4 times range
difference would suggest a massive mismatch.

>Before the test, I monitored the return port on the directional coupler
>on a Spectrum analyzer while seeping frequency from the sig. gen and
>noted the SWR on the commercial unit was lower than my version. (Though
>the measurement was not calibrated I could see the SWR was better but
>did not determine how much).

Then I would bet that your system topology is to blame. That is, your
line from the coupler and test equipment to the antenna is not
normalized out of the measurement as a network analyzer would do. And
when you shift from measurement to application, your line length
shifts such that your test match goes to hell. This implicates the
isolation of the sleeve - which is already in serious jeopardy by many
variables anyway. Your test scenario does not reveal the efficacy of
this isolation, it simply affirms that using the spectrum analyzer
establishes a suitable, but serendipitous arrangement.

You might add ferrite beads to the lead going to the antenna/sleeve
and move them along its length to test this hypothesis. This
prophylactic measure is also commonly employed as a necessary adjunct
to design.

David wrote:
"I am a little confused with calculation of appropriate length of metal tubing used in a sleeve antenna design (the 1/4 wave section)."

It should approximate the free-space 1/4-wave valie. The coax exterior, or the cylinder exterior,,= is the radiator, so interior velocity factor is not involved.

See the 3rd edition of Kraus` "Antennas", page 721 There are many other texts that may have better construction information, but everyone should have the Kraus book, or go get it now. "Transmission Lines, Antennas, and Wave Guides" by King, Mimno, and Wing is very good for sleeves as I recall, but I don`t have it at hand at the moment.

The commercial and homemade versions I have used had (2) 1/4-wave secrions. The antenna was actually a center-fed vertical 1/2-wave dipole in which the coax was fed through the lower tubular section. The top section was just a rod or wire.

These worked as well as ground plane =antennas, so we used them at VHF on small boats since there were no radials to get in the way or poke anyone in the eye.

The cylinder is slightly shorter than the rod at a 1/4-wave resonant length. You can experiment to find the resonant lengths, then put them back to back to make your 1/2-wave dipole.

From: Jim Richardson <warlock@eskimo.com>
Message-ID: <nu4713-hq5.ln1@fimbul.myth>
Source record: 69543

As I understand it,a colinear antenna, is a series of half wave elements, that are phase reversed (if that make sense) from one to the next.

Could you build a colinear of a single long line, bending it outa nd back, at 90deg, every half wave, with the bit sticking out (and back) being a half wave total out and back? would that result in the same effect as a colinear?

something like this.

Sonnich Jenson wrote:
"I`d like to listen to Danish Radio PS, on 1062 Medium wave."

A loop antenna is a good start for better signal to noise in a fixed location.

The 3rd edition of Kraus` "Antennas" says on page 217:
"The radiation efficiency of a multiturn loop or coil antenna can be increased by introducing a ferrite rod into the coil as in Fig 7-18."

My Telefunken Opus table radio has such a tuned horizontal ferrite loop stick to receive vertically polarized waves. Its azimuth is rotatable by a knob on the front panel for best reception.

External loops are available from many sources for use with your radio. If one of these is wired to your antenna terminals, only the position of the external loop need e changed for best reception.

For suppressing mobile noise, consult an expert such as A.A. Ghirardi.

Automobiles now come with fair radio noise suppression, but may have defects. The car`s engine compartment should be a continuous conductive shell which traps noise within. All conductors penetrating this shell must be grounded or they must be bypassed to ground (the car body) with caopacitors.

Your problem is weak signal and powerful noise. Good luck!

Best regards, Richard Harrison, KB5WZI

Yes!

The "there and back" is often seen as phasing coils on mobile UHF verticals. Also the same kind of logic as a colinear J pole (for example) that has the hairpin shaped thing about half way up the radiating section of the antenna.

You can also get colinear effects by using alternate halfwaves of very thick vs very thing elements (eg 25mm pipe and 2mm wire on 144MHz) but as one long "element" rather than bending it back and forth. (Yes the gain is lower for a given length)

Keep in mind that it is prudent to feed in the middle of the antenna, probably at one of the hairpins sections. Its a good place as somewhere along the phasing section the Z will be that of your feedline. If you feed at the end the pattern tends to skew away from the feedpoint.

1653. Balanced from unbalanced via a 100 ohm Q section - followup

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-03 14:25:47 UTC
From: Bob Bob <bob3bob3@cox.net>
Message-ID: <ckr713-tfd.ln1@p400bob.personal.cox.net>
Source record: 69550

Someone asked me how this antenna worked after I had built the Q section from two pieces of 50r coax side by side, using the centre conductors as an open wire feeder equivalent. The shields being joined at each end but nowhere else.. (There should be grounded at the bottom end and at some neutral point at the top - if any)

The antenna is a almost equilateral triangular shaped single quad loop with base/feed about 4 metres off the ground. The "almost" being the horizontal/top section is about 8 metres in length.

Well it works! I dont have enough of a power supply at the moment for doing any extensive on air tests. VSWR was 1.4:1 without much excursion at the band edges. This is what 4NEC2 said it would be. In fact I didnt have to cut it after following the modelled dimensions. It was surprisingly wide band I guess from the higher feed Z (rather than using a single 75r section)

I have only just moved here and there is a lot of noise about at various times of the day. (S7-9) I have heard stations across the US and maybe some Spanish speaking. Waiting for a PSU to arrive so I can try a little harder.

I didnt notice any VSWR changes or a change in feedline radiation (through PC/stereo spkrs etc) by coiling the coax at the base of the Q section. Indeed I did it because I was at risk getting tangled in the coax going to the trash can!

I expect high radiation angles BTW.

Cheers Bob W5/VK2YQA East Texas.

I cannot back it up with numbers but as I recall (with a fixed number
of elements) better results were achieved with a phasing harness. I
have always suspected that the elements closer to the source were
contributing the most. It sounds like a question that might be easily
answered by modeling.

The issue of selective vs full range broadcasting is a matter that has not
been decided either by client, company or possibility. There are plusses
and minus' to each.

Selective would entail less power but we are being told power of the fire
engine is not an issue.

Yes, the budget is rich with expected legal expenses. Since DHS has become a player in this, we are hopeful that we can get the necessary punch to overcome FCC and statutory issues.

>That being said, for this system to work, you have to blanket

Do we have to blanket or only blanket each locale, that is, the broadcasting stations of each locale?

Not only will we miss those no AM/FM listeners, we will miss those that don't have their radios on. An aggressive, road sign campaign is planned something like " Turn On Your Radio, It Could Save Your Life" type of thing near each incident site.

We are making no preference as to AM or FM as in that we will be attempting
to overbroadcast on each. The AM skywave issue is exactly that but the
system need not be perfect, only as perfect as possible.

The 3 meter limitation is clearly is a problem here, we haven't modeled a 3
meter yet. I also wonder what, if anything, LFAM gets us in terms of FCC
approvals and state regulations.

"Could you build a colinear of a single long line bending it back at 90 deg. every half wave---?"

See the "Super J" in the "ARRL Antenna Book", page 16-25 in my 19th edition. That is more or less how it is made. The two 1/2-waves, in-phase, are end-driven with phase inversion provided by a short-circuited 1/4-wave stub between them.

At frequencies higher than 2-meters, this would work for more than (2) 1/2-wave sections. The practical limitation is mechanical.

Hi Reg

The two pieces of coax are only meant to be a 100 ohm balanced Q section
to translate the antenna Z to close to that of the main feedline (50r).
I could do the same if I had some 100r open/ribbon feedline.

The outer conductors/shield should be at zero potential and as such
preserve the Z between the two inner conductors. This is handy in that
the coaxes dont have to be bound close together and could be fed through
a non metallic conduit without problems.

Have I made any sense?

Cheers Bob

there is no requirement that anyone listen to any broadcast radio. with the rapid growth of satellite radio there are even less people listening to either am of fm broadcast radio. add those who listen to cd's or dvd's and you get even less.

There are systems that are used for local road emergency notification, the 560khz one comes to mind, something along those lines would be the best bet, and add in signs on the backs of vehicles. i guess the real question is, what are you trying to do by overriding local broadcast stations? and over what size area?

Hi Ari

>>I always wonder whether broadcast at the most common IF frequencies
>>would be a viable alternative? (eg 455khz for AM) Legality issues aside
>>of course...
>
>
> I'm missing your point. Please explain.

I apologise if you already know the following! Its pretty basic radio..

Almost every radio receiver on the market works off the "superhetrodyne" principal where the incoming signal is mixed with a local oscillator down to an intermediate frequency. This makes receiver design a little cheaper as you can then put your expensive filtering at one frequency rather than have something that has to track the actual transmitted frequency.

For example a station on the AM band at 870khz is mixed with a local oscillator of 1325 khz (in the receiver) to get a difference of 455khz. If the station frequency is changed then one only needs to modify the local oscillator frequency. This is what the knob on the radio does!

The most common IF frequency for an AM radio happens to be 455khz so transmitting on that will mean you will be heard on all AM radios in close proximity. I dont off hand know the most common broadcast FM IF (maybe 10.7MHz or 7.8Mhz) but that should be easy to find. It is important to make sure that the IF of the fire trucks FM two-way radio isnt the same or you'll never be able to hear it inside the truck!

To "broadcast over" you would need to amplitude modulate the AM band 455khz TX and frequency modulate the FM broadcast IF frequency.

> Good advice here, will 20db do it?

FM is easier to do than AM. I'd factor in maybe 6dB for FM. You might be able to get by with 12dB for AM but the original station will make some small amount of noise under it. The important thing is that the person listening wil be able to understand the content.

Note that this is of course only relevent when transmitting on the actual station frequency.

> Yes, we are shooting for max overbroadcasting but the reality is it is a
> hit and miss proposition. Even the scenario of geo related
obstructions is

> a possibility.

Well it shouldnt be that hard to model. Do a AM and FM band coverage prediction over the freeways etc you are doing the experiment on to discover what the receive strength will be in dBm. (It doesnt matter what "gain" you make the RX antenna because it will be the same figure that is used for your overbroadcast) For every say 200 yard square take the mean signal of each, then take the 80th percentile as the signal you have to beat. If that was (say) -80dBm you want -74dBm (for FM) at the maximum operating distance (was it a mile each way?) You then reverse model that to determine what the TX EIRP of the thing on the truck has to be.

There are bound to be contract houses that will do this prediction for you. I use to work for one that had the software and I have some GPL versions myself. I cant do MF (ie AM broadcast) though.

> Being in a tunnel of course there werent really any
>>licensing issues.

> Is that peculiar to Aus?

The licensing issue or the tunnel? Tunnel rebroadcast is pretty common around the world. The company I worked for also did one in Indonesia. Its also used in underground mines.

> Very nice, congrats on that. Was it Yagi technology or fractal?

Err, the leaky coax was just a 2km run of an Andrews product that has leaky holes in the shield. It was fed in the middle with a wide band splitter and terminated with 50 ohmss at each end. Its quite a common thing to do in underground environments. (Buildings too) Handy for two way radio as well as cell phones.

The AM thing was just a very long terminated (600r) wire.

None of the above are yagi or fractal

Cheers Bob

I see from an Australian newsgroup that somebody is seriously
considering and making plans to cover the whole continent using a pair
of longwave, 1-megawatt, broadcast transmitters.

The antennas are to be Professor Hately's CFA's which perform
according to Maxwell's 4th Equation.

Should somebody break the bad news to them before its too late? Or
should we wait and have a good laugh?

Reg.

And you've offered this is during an obvious emergency? :
1 Why would they play music loudly in an insulated car when doom is
on their heels?
2 Why would neighbors complain of noise telling them they were about
to be die?

Richard's description adequately suits:
Local - that would reach out approximately 1 mile and "overbroadcast"
to those immediately in danger within a stationary site.

Your objections are more tailored to suit your solution than the
problem.

While Florida may have laws to this effect, in fact they are
unenforcable because of federal preemption for all radio matters.
Still illegal, just the wrong enforcement entity. A state or locality
cannot for example legislate on TVI matters (though many have tried.)
When they try, the FCC will send a notice to the locals that they are
in charge and will handle enforcement. Unfortunately the FCC is
unwilling to get involved in the matter of private contracts such as
antenna exclusions in housing developments.

That said, be aware that when it comes to radio useage in the US, the
FCC is actually NOT the ultimate authority. They are responsible only
for those frequencies which a military controlled panel has ceded to
the FCC for administrative purposes. I can't remember the name right
off hand, but during my federal career, I had to work with them and we
actually were able to override an FCC allocation because it interfered
with a military application. While the FCC played ball with the DOD
outfit I worked for, the ultimate beneficiary of that allocation (a TV
station) sued and the matter wound up in Federal Court. The court

reaffirmed the DOD's ultimate sovreignity in this matter. It
ultimately got resolved by some allocation juggling when a combination
of the Court, The FCC and the DOD gave the plaintiff some "religion."

Hi Richard

About 45 years ago, I designed a vertical collinear array of dipoles for
1.7 GHz (actually 1,700 Megacycles then). That antenna was a series 1/2
wave sleaves located below a coaxial dipole. The nice aspect was the
simplicty of its feed. The "beam squint got fairly great since there were
alot of passively excited 1/2 wave elements
I had capability of measuring the radiation patterns from the antenna, so
I can assure that the concept you propose will work.

Hi Ari,

As you have described it, and have seen the discussion in regard to
the need for ERP - you are so deep in the debit column with AM power
EQUAL to a local broadcaster, that to climb out of that hole would be
prohibitive. READ: no fire truck has a power plant sufficient to
cover both the antenna system losses AND "overbroadcast" as you
desire. And this is for ONE station only. Imagine your broader
mandate to "overbroadcast" all local stations and that hole just gets
deeper.

>Am I way off base here, can any antennae, fractal or other, or any AM

Hi Ari,

The various pieces of this jigsaw puzzle is beginning to reveal a
picture here. With the introduction of two governmental
organizations, and their regulations, your "plan" has all the
appearances of being suitably crafted to work on paper. It responds
to the individual issues that any squinty-eyed bureaucrat would demand
be satisfied for his postage sized turf, but in the overall it would
fail miserably, or drive costs so high as to be tainted with the plea
that "aren't people's lives worth the price?"

Let's see, the original spec calls for a disaster situation that is
confined to within 1 mile; that demands the local population be
informed; that over-rides their usual paths of communication; that
reaches them even when they are not engaged in listening.

As already pointed out, big sound trucks do wonders, and have worked
well since the beginning of the last century for this purpose. That
kids inside their home can hear the ice-cream truck a mile away is a
testimony to this simplicity.

Knocking on the door of the local broadcasters and commandeering their
air-time has a time honored tradition of working quite well too. This
involves no more time than getting that expensive mobile power plant
rigged with wide band transmitters working into hugely lossy antenna
systems into the same danger area. After-all, you could as easily
call the first most obvious radio station as them, and you could be
calling the others before they even got on the road.

The solution demanded is that all radio stations respond to a disaster
network alert and citizens tune to the Civil Defense frequency when so
warned by them. Is this another administration cut-back that was
shelved as one of those unnecessary "entitlements?" Have they clipped
all the wires to those old Air Raid sirens? When did the lights go
out in FEMA?

==========

The jacket of coaxial cable is usually a soft grade of
poly-vynil-chloride, PVC, which can have a dielectric constant
anywhere between 4 and 6.

The velocity factor along the outside of the coaxial braid depends on
the thickness of the jacket. To make much difference to the VF it has
to be an inch thick or more whereas it is probably only about 0.6mm.

I will have a guess and say the VF is about 0.95. You can forget
about it.

I don't worry much about coax feedline impedance bumps at HF
frequencies.

> But I have built my
> own coax relays from regular relays and have gotten adequate performance.

I've done that a number of times with $5 Potter & Brumfield open frame
relays and never had a problem. In 50 ohm circuits. My big concern is
switching HF kilovolts with $5 relays which is a whole different
problem.

OhYeah, that's what I've been looking for. Tnx Cecil! I Googled 'em and landed on the Mouser web page which lists the Omron LYs. They're good for 10-15 amps @ 2 kV AC and for only $6-7 each. Should work fine although I'd like to have higher voltage ratings. Not much to lose by trying a couple of them to find out if they arc in the 110% humidity we occasionally get around here.

The LYs are designed to minimize humidity problems. The
air gap is replaced by some sort of plastic separator.

My experience with AM (on the aircraft band) is that two transmitters
at the same time yields a horrible squeal and nothing else. The louder
station (usually on the ground with hundreds of watts) has no particular
advantage over the other station (usually in the air with 5-10 watts).
In other words, there is no effect like FM capture.

They sound like they'd definitely do the job but so far I can't find a
U.S. source for them.

> Without necessarily endorsing that particular product, there are a few
> interesting points:
>
> * Switching in HF antenna couplers and filters is now a recognized
> market.

> * Reed relays can handle this kind of service.

Exactly. They're showing up everywhere in recently-designed ham
equipment - to the 2kW level and beyond. Big amps, big autotuners, etc.

In prior times the coax could be remotely switched but the only relays which could handle high RF voltages were pricey vacuum relays. It's the recent advent of these inexpensive new type reed relays which led me to reconsider using end-fed half-wave verticals.

> * Coupling into the coil can be a problem, which may suggest making your

> it can tolerate.

I don't understand the shielding/loss problem. I wouldn't be using these relays inside equipment where shielding as such might matter. How how significant are these losses? I'm switching the bottom ends of more or less resonant wires from wire to wire and from tuner to tuner in some arramgement or another TBD. All of it out the yard where I hope I radiate as much RF as possible.

> More details and a data sheet at:
> http://www.crydom.co.uk/Webpages/archive-new_fully_screened_rf_relay.htm

Nice specs, I'll continue the hunt for a source.

Neat. Even if they do arc the barrier could always be replaced with a
bigger and better homebrewed barrier. Off to the relay store and pass
the epoxy . .

1) to grab those that are listening to AM/FM, it is still a hyooge market,
2) client request, 3) DHS preference 4) the number of people alerted by a
sign/sticker and independent warning channel is much less than both that
and AM/FM, 5) the possibility that once the AM/FM FCC/NAB bond is broken, a
precedent could be set for cell, sat, threading messaging, etc 6) spinoff
tech for local/reg/national emergencies.

Excellent point, in my research I saw this handoff or spectrum management
authority of the DoD and it makes sense. This is a serious, additional
consideration and is all the more reason to get the DHS' blessings.

Thanks.

No one, in the end, will care about that, Richard, it's buzz words. The
economic hooks are in lessened liabilities and coordinating better
emergency evac and site control plans. Money talks here.

> Let's see, the original spec calls for a disaster situation that is

Yes, but as we recently saw, things left to the "if come" often don't "come" ask FEMA. The plan needs to be in place and the control out of the hands of anyone except local/reg/national authority.

> The solution demanded is that all radio stations respond to a disaster

Nothing wrong with that if you know where to tune. I don't, come to think of it.

MOF, it's an idea that came up over dinner during FEMA/NOLA, don't know about the sirens, all I do know is once FEMA got there, they shutdown most commo inc police in some cases. They want total control so this p[iece has more play at the immediate response (local/state) levels.

Dave,

First I am called Punchinello, and now Don Quixote is implied.

Yet you have repeatedly said "Reg is correct".

The only thing I have ever asked is to change the NAME.

It is the NAME itself which causes ill-educated IEEE members and befuddled university professors to become old wives. They are reduced to CB-ers who perhaps can be forgiven for being fooled just by a NAME. They actually believe the thing measures SWR on a line which does not exist. Or they find a line which does exist but on which it is impossible for the thing to measure anything because it is located in the wrong place. Their contorted imaginations somehow allow them to argue interminably between themselves but without ever coming to sensible conclusions on which they can agree. The evidence of battles about waves, reflections, re-reflections, virtual reflections, conjugate matches, etc, etc, is littered around these newsgroups. And it's all due to a misnomer.

Just change the name of the so-called SWR meter and 50 years of bitter warfare will revert once again to blessed peace and an understanding of how things really work. Sack your lawyers.

And if anybody should think I take all this seriously then think again. ;o)

From: Lance Orner <lance@orner.net>
Message-ID: <slrndk34tv.61o.lance@localhost.localdomain>
Source record: 69472

Just getting back into HF, and I'm trying to get an antenna up on my small lot which backs up to a hillside. There are two locations available without erecting more infrastructure. One would be about 20 feet up at the base of the hill, and the other is about 50 feet up the hill, but only 10 feet off the ground.

So the question: Is it more important to have the antenna farther from ground, or father up the hill but closer to ground?

In the future, I'd love to put a tall antenna at the tallest part of the hill, but I'm looking for something temporary right now.

Thanks.

Are you saying that if I am attempting an overbroadcast on, say, 680 AM and
the station is doing the same, and I am 12 db + greater, that all we will
get is squeal?

Reg, the SWR meter may be smarter than you think. Here's
an experiment for you. The system is lossless.

XMTR--a--1WL 50 ohm--b--1WL 75 ohm--c--1WL 92 ohm--d--load

An SWR meter calibrated for 50 ohms will read the SWR on
the 50 ohm feedline when installed at points a,b,c, or d.

An SWR meter calibrated for 75 ohms will read the SWR on
the 75 ohm feedline when installed at points a,b,c, or d.

An SWR meter calibrated for 92 ohms will read the SWR on
the 92 ohm feedline when installed at points a,b,c, or d.

Now Reg, you have to admit that an SWR meter that can read
the SWR on the 92 ohm feedline when installed at point 'a'
is a darned smart meter. :-)

One signal is the Beat Frequency Oscillator. I am amazed
that no one has thought of this perfect solution before.

If Morse code were required for all driver's licenses, then
all you have to do is furnish a CW carrier wave. The two
signals would mix and the squeal would be Morse code which
would carry the emergency information.

1718. Emergency Messaging, AM/FM *On Locomotive*

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-03 21:19:42 UTC
From: Ari Silversteinn <abcarisilverstein@yahoo.comxyz>
Message-ID: <1lihotn31d6fk.a79lqxn15md6$.dlg@40tude.net>
Source record: 69463
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.misc,rec.radio.amateur.equipment

DHS has proposed a change in scenario. They want an on locomotive alerting system that could be commandeered and driven at, near or about a disaster site. Everything else stays more or less the same, overbroadcasting on local AM/FM, power off the locomotive, selective or full frequency broadcasting, train (s) to be in motion at all times. 20-30 second messages that would also combine a message to be aware that a locomotive (at speed) will be flying by the at grade crossings.

Comments?

A physics guru might say that if it's a photon, its frequency is E/h unless one of the virtues of being 'virtual' is that its frequency may or may not be equal to E/h. Perhaps it's greatest virtue might even be that you can attribute any physical characteristic you want to it - not unlike some of the other virtual entities. ;-)

I don't already know it, Reg. The impedance of the load is
unknown so the SWR is unknown until measured.

if this is for real time notification you don't have time to bargain or to
find an unused channel... and who would listen to you anyway if it was
unused? how often do you turn the knob on your car radio??

what about the emergency broadcast system? that would seem to be the
'proper' method of emergency notification, its already set up for all sorts
of local, regional, and national notifications.

There are a couple of frequiencies for unlicensed low power am stations. You can see them in use by real estate folks selling houses. There are no commercial stations on the frequency.

Impractical, for the same reasons cited earlier. What's wrong with
electronic message boards on trailers fitted with sirens and, if deemed
necessarily, a very large guy with a gun to maintain interest.

You may find that sci.electronic.misc or sci.electronic.design may be more
relevant, since it's commercial/military and not amateur. Mind you, they may
also be less polite.....

Ken

Yes, that works OK. You have acheived your objective.

My only comment is that the inner coaxial conductors are very thin and depending on length they may be a little lossy. You could use a twisted pair of thicker wires insulated with thin plastic which would have approximately the same 100-ohm impedance. The actual impedance is not very critical.

This would also eliminate stray capacitance of the coax outer conductors to their surroundings. Although that is not likely to cause much trouble anyway.

Reg.

Actually the DOD does not have any authority over radio spectrum. There are two federal agencies that do. One is the FCC, which we all know and love, the other is NTIA, the National Telecomunications Information Agency. NITA controls all federal radio frequencies. Since the DOD is a Federal Agency their frequencies are controled by NTIA the same as the FBI, CIA Secret Service, Dept of Homeland Security and any other federal alphabet soup agency.

Dave N
a FCC and a NTIA user

Why a loco anyway? It would appear to be the mistaken assumption that anything that big must have power to burn on anything plugged in by a user. Not the case - the power from a loco is, not surprisingly, applied to the tracks. The electric generators used for powering gear other than the train's vitals are not high power.

Well, he's not a troll in that he's making it up as he goes - it appears he
really is hoping to do for his company what he says (source: Google).

However it's a job which really equates to:
<Government fleeces tax-payers>
<Bureaucrat gets hold of budget allocation>
<Bureaucrat needs to succeed - ie. unload allocation>
<Ari and co. want to be under the hopper when the jackpot payout commences>

A valid way of doing business, but still a crock.

Ken

1744. Re: Balanced from unbalanced via a 100 ohm Q section - followup

Mmm okay, well considering the rest of the feedline is RG58 I guess the matching section has less loss per unit length! <grin> (The Q section is 3 point something metres long - 1/4 wave at 0.66 vf)

I havent been playing with HF that long. I must admit though that I tend to ignore the losses that I would worry a lot about at VHF/UHF.

Oh BTW I tried one of your pgms under Linux Wine the other day. Dies with some kind of DOS memory alloc error or something. I'll make a note of it next time and do a little research if your interested.

Cheers Bob

1745. OT: Military Radio Question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-04 00:26:04 UTC
From: Rod Maupin <gridman@ywave.com>
Message-ID: <11k3j0s7dujl92a@corp.supernews.com>
Source record: 69491

I posted this on another group, but you all seem really smart here.

I have a military radio (PRC-1099) and a battery. I want to buy a power supply that will power the radio but which can also be used to charge the battery. The radio needs a 12V power supply to run. The battery is a lead-calcium type, and is supposed to be charged at 1A for 5 to 6 hours.

Buying a 12V power supply is easy, but do supplies normally have a variable current output? I am not an authority on power supplies or charging batteries, so I need some help here.

Thanks,

Rod KI7CQ

I have developed a simple tool to assist NF measurements by performing the calcs in a two stage cal/measure process, and documenting the test.

So, if you interest in antennas runs to overall receive system performance, you may find this calculator handy.

Works in IE and Firefox. Tested to a fair extent, but it could contain defects... if you find any, please let me know.

That would be much easier, simply sweep a modulated oscillator across the band. With a couple of adjustments it would be easy to emulate a train whistle, a somewhat universal warning.

Wonder no longer, because broadcasing at IF frequencies has been for year the standard in the US. In spite of some rather silly speculative posts, this mechanism has proved itself for more than 10-years here.

In a confined space such as a tunnel, a transmitter of 10-watts more than sufficint to get the job done, and using nothing more sophisticated than a simple wire radiator running the length of the tunnel.

In Boston, we also retransmit commercial radio broadcasts into our tunnels, but that requires equipment dedicated to each radio channel that we re-broadcast, and that becomes very costly after 10 stations or so, hence there is a limit.

The real challenge is in maintaining emergency communications to the outside from within our tunnels. All are serviced by the traditional leaky coax that runs along the top of the tunnel, but considering that all of these emergency services operate on their own indepdendent frequency bands, so servicing them simulteously becomes somwhat problematic. particularly when hand-held, low power devices enter the big picture.

All agreed, but that is in a tunnel, which has the advantage of not having
to overcome the still-received commercial stations. The OP wants to do this
out in the open, anywhere, any time. He also wanted to do it while driving
at high speed for some reason, but I think he's quietly shelved that part of
the idea.

Cheers.

Not that simple Rod, as the battery charges, and the voltage changes, current from most supplies follow the voltage. What I mean by that is that with a discharged battery you get more current than you desire at the start of the charge cycle. I use a device that is used to charge model airplane batteries. The same supply you use to power the radio will power the current limited charger.

Check your local Hobby Shop or one of the on-line sites. I bought one for about $49.00 that will charge Gel Cells, Ni-Cads, etc.

Of course you can simply use a wall wart, but the money you think you saved will be spent in battery replacement.

What are the constant voltage charging specs on the battery? (if any)

Rod

For what reason is it needed to require the battery to be charged within 6 hours? If it is practical to charge the battery "overnight", the requirements could be much less expensive.
There is alot-alot of information on the Internet about charging lead-acid batteries. The lead-Calcium is the type cell commonly used in most automotive autos today.
If this was my radio, I'd use a wall wart with a 12 volt lamp in series between the wall wart and the battery. . A 10 volt DC, 1 amp wall wart would probably be close to proper for this radio. The series lamp will limit the charge rate.

If the battery terminal voltage is restricted to being no higher than 14.8 volts,the battery will not boil off its electrolyte.

Jerry

1758. Connecting several bandpass filters.

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-04 07:20:06 UTC
From: SH <sholby@hotmail.com>
Message-ID: <43422d26$1@news.wineasy.se>
Source record: 69505

Hi

I have come up with one of those crazy DYI ideas which I would like to try to implement but one thing still remains.

I have two UHF (TV) arial pointing in different directions and would like to connect them together through BP filters to minimize noise.
BP = Bandpass
Antenna 1: UHF channel (Europe) BP 1 ch 22-37, BP 2 ch40 -44, BP 3 ch 49 - 68/ or high pass
Antenna 2: UHF channel (Europe) BP 1 ch 21 / or low pass, BP 2 ch38 -39, BP 3 ch 47

I have found formulas to design each section of BF but how to you connect several BP filters in parallel??? I have investigated some old TV filter and they have a coil (12 WDG) in and out of each BP section but is that the way to do it and how does it influence the design of each BP.

The only approach that I can find is to split the signal into three (- 6dB) then feed each into a BP filter and the Combine them again (-6dB). This will result in each BP section seeing 75 Ohms as they shouland they would not interfere with eachother. Ofcouse i would need a 20 dB amplifier to fix the loss.

But is there a better way.

Best regards

Svend Holby

It's probably more reasonable to notch out the primary interference
than to get that fancy with filtering. Eg if you have ghosts from an
interfering channel 21, notch out 21 on the offending antenna. It's
easier to make a highly selective notch than a bandpass with steep
skirts.

> I have found formulas to design each section of BF but how to you connect
> several BP filters in parallel???

A set of notch filters would be used in series. I believe this is
what cable companies use to control access to premium channels.

Actually, it's not.

What made you bring up tracks anyway -- my reference to the
tracks on the lake falling in? My point was that the locomotive is
going nowhere there aren't usable tracks.

On a diesel-electric locomotive, the generator's output is
applied, not to the tracks as you seem to think, but rather through
control circuitry to the stator around the axle. It's rather amusing
to see a repair yard worker with a set of wheels-and-axle (they're all
one single piece, in case you didn't know) clamp a stator around the
axle, connect a battery with a pair of short jumper cables and walk
the whole arrangement across a concrete floor as though he were
walking the family dog.

BTW, at 4,000+ horsepower, you could plug in nearly anything a
user might want, given proper appliances and the right plug. :-)

Jerry,

The 10 volt DC wall wart is unfiltered and the designated voltage is 10
vdc rms? So it would be supplying 14.1 volts peak?

Trying to understand how the 10 volt supply will charge a 12 volt battery.

Thanks.

Chuck

And what are these messages suppose to convey?

The target audience already knows it's screwed.

We all (outside the screwed zone) saw the blizzard of useless
"messages" the government(s) issued during and after Katrina.

Just what I need to hear from a locomotive blowing by at 50 mph:

"Hi! We're the government and we are here to help you."

The best that came out of post-Katrina was from self-help and
assistance from non-government organizations. And, the
government even thwarted some of that.

The inmates are running the asylum:

Like I said in another thread, "Emergency" implies IMMEDIATE (not planned) danger to life, limb, or property. It seems that, in your proposal, you are PLANNING to use these frequencies instead of more appropriate ones. I would think that you need to create (and supply) a system that is isolated from broadcast frequencies.

Lance,
The 'first' thing that comes to mind is to get the antenna
as high as possible. Then theres the 'second' thing that comes
to mind which is which is going to be more practical to do? I'd
go for the highest to start with. Nothing says you can't change
it later.

Suggestion: Why don't you also broadcast such "emergency" information over
the entire spectrum of wireless network frequencies? That way, you could
post the information into every Usenet group on the globe. Just like you
have done with these postings.

1772. Re: Military Radio Question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-04 15:04:13 UTC
From: Rod Maupin <gridman@ywave.com>
Message-ID: <11k56fd3oubmsf6@corp.supernews.com>
Source record: 69519

The PRC-1099 manual just says what type of battery to use. When I bought the radio, the battery came with it.

Actually, I was incorrect. The manual was talking about using different battery types, lead-calcium being one of them, but on the battery it has the following information:

On the side

Battery, Rechargeable BB-586/U
Nickel Cadmium, Sealed
13.2 Volts, 4.0 Ampere Hours
At 0.8 Ampere
Bren-Tronics, Inc.
Commack, New York

On the top

Charging Instructions
Recommended charge rate is 1 AMP for 5 to 6 hours. Charging temperature should be 40 deg. F. to 90 deg. F.

Thanks for the help,

Rod KI7CQ

There is an element of both I agree and the locomotive environment, except in the newer ones, can be a bit hairy. Whether or not the concept is valid, that's for DHS to decide and they already have.

The driving force behind this, imo, is that during NOLA no effort was made to use the RR as a means of evac. Several of the lines offered but FEMA refused. Instead, Carnival made off like a bandit with 1/3 full ships but 3/3 full government pay.

In order to evac, the RR would need to run flat out and with an evac traffic surge, crossings become more critical.

Locomotive because of the need for a manual override by the Head Engineer.
CSX claims they can provide access to 1,000 watts.

Know of the NTIA but I believe that what is the reality is that the mil
gets first dibs on frequencies, then hands off the rest and in a state of
national emerg, they can pretty much takeover the airwaves.

Hi Ari

I always wonder whether broadcast at the most common IF frequencies
would be a viable alternative? (eg 455khz for AM) Legality issues aside
of course... This would make frequency selection a little easier to
engineer. You wouldnt have to divide your power budget into many
operating frequencies as well. Problem is that you'd need a lot higher
ERP especially since car mounted radios tend to be better shielded than
portables. (You'll need to experiment some)

Seems you've drawn a blank then too. On your own sentence which is
the point I made significant. That you missed on both accounts is
doubly indicting. Do you have a relative in Texas that is sweating
bullets now?

You might want to point out that if you do not modify the Aston, such
practice will cause a problem with in the Aston.

Richard, Richard, Richard! :-(Read your last sentence. Do you see
the error??

"Do you have a relative in Texas that is sweating bullets now?"

There is a GLARING ERROR in it!!!!! It should be ...
"Do you have a relative in Texas WHO is sweating bullets now?"

A relative is a PERSON not a THING: a WHO not a THAT!!

Tch, Tch,

Hi Chuck

Yeah, the wall warts are marked with output voltages that are only approximate. The real test of the wall wart would require that it be hooked up to charge a capacitor. That will indicate the maximum voltage to which the battery will charge.
The average Lead-Acid, Calcium, 12 volt battery will require about 14.8 volts to begin boiling out its electrolyte.
Charging batteries might not be "rocket science", but it can get complicated. There is so much good info available on the Internet that it would be wrong of me to pretend that I'm an expert only because I understand a little about the subject.
A wall wart, marked as about 9 or 10 volts DC with a 12 volt bulb in series with it, can be used as a decent float charger. I'll assume that anyone reading this group will see the technology behind this low cost, readily available system.

The 723 in the Astron will eventually fry when you remove AC power. A simple fix is off of pin 4 that normally goes to the wiper of the voltage adjustment, cut the land and bridge with a 10K 1/2 watt resistor.

I have probably modified over 50 of them for our EOC sites and have never lost a PS.

He wasn't referring to your finance budget, but your energy budget. I
hesitate to say it can't be done in any practical sense, but that's my
thought. The idea of one poster to transmit on the IF's is a good one but I
didn't suggest that because you'll also kill your emergency services comm's.

Incidentally, do you plan to have every loco in the US fitted out or are you
going to fly the loco's to the incident site to do their stuff?

Cheers.

No, but forewarned is fore armed. :-) Your spec's are a bit nebulous, to say

the least. I'm not accusing you of having no clue, but I'm damn glad DHS doesn't use tax-payer funds from this part of the world. This is an exercise in getting rid of funds grabbed during a crisis, when the opportunity arose to expand the empire. Standard bureaucratic function.

Cheers.

I'm really not criticizing you, per se, but I don't think the concept is
well thought out.

You refer elsewhere to this being an auxiliary warning system on a loco -
level crossing lights/bells/boom gates not enough? They usually are, so why
the worry now? (Okay, we know it's the moolah....).

You also refer to 1,000W being available - it's just not enough for what you
want to do. Period.

Good luck with them getting their act (I would have said something else!)
together, but don't bet the bank on it. I'm actually an ex-bureaucrat myself
and to call me cynical of governmental abilities would be an understatement.
But if you do come up with something useful (I bet it ends up being a

spin-off rather than the initial concept seen here), I hope you get something out of it.

Cheers.

Hi Ken,

His terse reply refers to the public coffers - troughs - open for this fabulous pork barrel feast. You know, crack dealer capitalism.

Nothing has to actually work, or be useful, or even be used. It just has to generate paper in one direction, and cash in the other. Ari is mining us as a dry run for all the terms, shortfalls, and fits to the jigsaw to rummage up into a proposal.

No, but then again you can save the cost of the diodes and the associated voltage drop when operating from the power supply.

My concern was that someone with less knowledge than yourself would simply parallel the battery with the Astron power supply.

Your initial message did not have a caveat for those that thought it might be that simple.

It can be found under the section that allows a transmitter as long as it is
less than some number of milliwatts per meter.

If you really need the exact section, I will drag out the regs and get it
for you.

That is part 15 and it isn't just a couple of frequencies, it is any frequency in the AM broadcast band (and the FM broadcast band, for that matter).

Specifically, 15.219 allows operation on any frequency in the band so long as (a) the input power to the final stage is less than 100 mW and (b) the antenna "system" (radiating element, coax, and ground lead) is less than 3 meters long.

15.221 also allows operation with an unspecified power level into leaky coax with a field strength limitation.

Power is not milliwatts per meter. Power is milliwatts. Field strength (also an allowed measurement) is in volts per meter.

The OP said that there were a "couple of frequiencies(sic)for unlicensed low power am(sic) stations." That implied that there were a couple of frequencies that were unused in the AM band by commercial stations, and I just wanted to have a reference to WHAT they were and WHERE in the regs they were delineated.

In this case the milliwatts per meter refers to frequencies stated in meters.

Volts per meter only applies to the E component, the magnetic component is always stated in amps per meter.

I will get back to you on the specifics. I am pretty sure that my brain is not suffering from a senior moment as to my recollection of the regs.

Ben Jackson has some good points. You need not worry about audio, usually, as the FM capture takes care of the weaker signal. So, filtering the video carrier and near sidebands is all that is necessary.

However, in answer to your question, the way you connect bandpass filters in parallel is with power dividers, amplifiers, and power dividers again, backwards as summers. Otherwise, controlling the out of band input and output impedances of several in parallel is a monumental, but solvable task. Spice, anyone?

Hi Fred,

Is this to suggest that for 300MHz it is 1mW total input power as say
compared to 1MHz allowing 300mW?

This would be uncharacteristically generous of the FCC whose
regulations would ban emissions from dummy loads.

Seems it would hardly serve Ari's search for pork, but I suppose
grantsmanship would jump at sending a marathon of runners through the
spill area - each carrying sub-Watt handi-talkies to provide the
aggregate power, and spectrum, and lung volume necessary to "get the
warning out."

Richard the value changes per band and is stated in part 15. For example in the broadcast band the formula is 24000 /F for microvolts at 1000 feet.

There are certain bands that no emissions are allowed from a low powered device. For example setting up your neighborhood micro Rap Station on 121.5 MHz (aircraft emergency) would probably bring a swift shut down.

I am still searching for the reg that allows fixed information stations. IIRC they can be run on 530 and 1750 KHz. I know in the past I had looked at the regs and the particular station I was researching was indeed legal.

In the low freqs (140 KHz area) you can run up to 1 watt CW with out a license.

Not quite. That is the limit in 15.209, with the following caveat
"...except as provided elsewhere in this subpart..."

Elsewhere in the subpart (15.219 and 15.221) we have the limit for the band
525-1705 kHz. (AM broadcast band) the 100 mW and 3 meter antenna restriction
OR a 15 uV/m restriction at a distance of (47.715/(frequency in kHz.))
meters (which is also lambda/(2 * pi)) from leaky coax.

BTW, it is 24000/F uV/m at 30 meters from 490 to 1705 kHz., which is more
like 100 feet, not 1000 feet (15.209).

The problem is that anything that is speced at this point is bound to be
changed by FEMA, DHS, FCC, and God knows who else. The idea is to start
somewhere and march forward beginning with the writing of a "white paper"
that can be shot full of holes.

Truth is, I was thinking about reserved but not yet assigned AM/FM
frequencies.

Considering that we have many technologies in use, mof, all technologies
that are not in development are in use, this is a load of horseshit. If we
build it to spec, whatever that spec is, it will be proprietary and how and
when they use it is not in our hands.

Hi Jim

I actually had a quick look at that for trying to run Ari's 4NEC2 under Linux. Since it calls the DOS shell to run the calc I was hopeful. Cant remember if it worked but was more concerned about how to call it from the GUI under Wine. (ie how to call a Linux pgm from a W32 pgm running under wine!)

I tend to use my wife's W98 machine when I need to model things (shame on me!)

Many tnxs for your feedback.

Cheers Bob

Hi Steve,

No you can't bleed off charge. The earth can supply an almost infinite
amount to replace any that you would have bled off.

A sharp pointed rod is more apt to attract a lightning hit than one
that is blunt. Sharp pointed rods are installed to try and provide a
preferred path for lightning when it does strike.

You can not prevent a strike from happening in an area.
A structure above about 150 feet is just as apt to be struck on the
side as it is the top. It all depends on the way that the step leader
moves in its steps.

You mentioned putting a loop in the coax at the bottom of the tower to
help raise the impedance of the line. However putting a loop or coil
in the line may result in worsening the condition. The coil now can
act as an antenna and increase the pickup of the high magnetic fields
from other lines, tower etc. in the vicinity. So it is generally not a
recommended thing to do.

Bring the coax down to the bottom of the tower and ground it there to the tower ground. Then run on the ground or buried to the shack. At the shack entrance place surge arresters and ground again to a large ground field. The ground field should also be tied to the tower ground filed.

Thanks for both you answers its nice to now i stil remember some theory
eventhough its 10 years since i read some UHF theory (Ended up being a
programmer :-))))

I think ill go for the notch version. I have made a lot of them and they are
easy to build but I've noticed that it seams that 3 notches (adjusted to 3
diff freq.) is some kind of limit. When i put in no. 4 it seams that the
overall loss increases.
Do I remember correctly when i state that 2 nothes on the same freq. should
be a 1/4 wave apart???

Best regards

Svend Holby

I think you will find that the FCC has the FINAL call on frequency band usage. I can't see them authorizing such intrusive use of the normal broadcast bands, especially after the broadcast industry gets wind of your proposal.

From a technical standpoint, broadband transmission of a signal is not hard. A simple VFO sweep of all the normal broadcast bands is all that is required. Obviously, the appropriate modulation techniques would have to be used for each band.

Another approach would be the use of a local (LOW power) sweeping UP/DOWN converter. In this method, you could transmit a specific (authorized) signal from the site. This signal would be received and detected by a local receiver. This information would be used to modulate and rebroadcast the signal within the vehicle. However, this would require onboard equipment.

I still think that your biggest hurdle will a legal one.

Wayne, KC8UIO wrote:
"I still think your biggest hurdle will be a legal one.

When life is at risk, there are no prohibitions on radio transmissions.

Disruption of all normal channels is unecessary and undesirable. Some won`t be tuned-in and won`t immediately get the message. Nearly everyone has eyes and ears. Sight and sound are useful to communicate.

Air horns as used on locomotives are designed to get attention. They are heard at great distances.

Illuminated message boards are used for travel information along hiways. They are also used for advertising on the Goodyear blimp and other vehicles. They are towed behind airplanes.. They can be programmed by recorded media, wire lines, and radio, even satellite.

Where I live, we have a traffic control central which monitors streets and hiways using video cameras. It gives travel conditions and approximate times required along various routes.. This is reported on the illuminated displays and by radio and TV stations.

A display can`t do anything about hiways clogged when people are stampeded by officials telling them to get out of town, other than warn them away from the clogs.

Some people don`t have the means to get out of town. Others rush into what becomes a huge parking jam. We don`t have room for all the vehicles on the hiway at once. It`s a free country and we cant enforce private access to roads and streets.

We have marked evacuation routes. Everyone can`t use them at the same time. When they try, nobody moves anywhere fast. When officials order an evacuation, they must also advise rail times and places of departures. Bus schedules must be given too, to keep some of the automobile load off overcrowded hiways. Airline information needs to be broadcast too. The transit central`s website needs to be broadcast for internet access.

We had an "emergency broadcast system" ehich tested OK. It could be activated for purposes besides an atom missile. We had air raid sirens that could be used to alert people to tune-in for vital information. We don`t need yet another untested system.

Best regards, Richard Harrison, KB5WZI

Hello

I would like to have some help. I have a school job to build a medium wave antenna omnidirectional for a area 60km radius. the frequency of the station is 999KHz.
Where can i find some material to do this.

Tanks

Which mat make this impractical in the short run but there has been
discussion about mandating this type of installation. I have my doubts but
then we have seat belts and airbags.

I did that with two 80- or two 40-meter whips mounted about two feet above
the cab (pointed straight forward and straight aft) of my pickup truck
(which has a topper on the rear at essentially the same height, and it
"got out" like gangbusters!

Unfortunately, one day the forward-pointing whip exactly snared the loop
on the rope used to close the garage door, and several things broke!
(But, fortunately, it didn't damage the garage door.)

1857. How feed an extended half-square?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-05 18:49:48 UTC
From: mcalhoun@ksu.edu
Message-ID: <di178c$a2v@unix1.cc.ksu.edu>
Source record: 69404

I have room to erect a "half square" (aka upside-down phased verticals?)
20-meter antenna to be fed at one corner (low-impedance location; attach
50-ohm coax) or at the bottom (high-impedance; use a matching network):

```
A B
+--------------+ 1/2wave long
| /| 1/4wave high
| / |
/ Matching Network
Coax
```

Unfortunately, I do NOT (because my house is in the way) have room
to make it a more-balanced curtain:

```
A B C
+--------------+--------------+
| /| |
| / | |
/
coax
```

However, if I extend the horizontal wire and leave out the middle
"vertical" (because it would dangle onto the roof), I have room for
four vertical sections in a space that should have five:

```
A B C D E
+--------------+--------------+--------------+--------------+
| | this part will be about | |
| | 10 feet above the peak | |
of my house
```

Observations:
* Line ABCDE will be about 28 feet above ground.
* There is almost no AC wiring in the roof part of the house.
* The incoming AC power line terminates reaches the house at about a
20-foot height (i.e., some 8 feet below the ABCDE line) about halfway
between points B and C and at about a 45-degree angle with line ABCDE
* A lot of tree- and ladder-climbing will be involved, so I'd like to
keep the "cut-and-try" to a minimum.

I've never done any antenna modeling, and I've never had any "feel" for
antenna phasing (EE degree notwithstanding), but I suspect feeding it
at the original corner (B) will result in somewhat unbalanced currents
almost everywhere.

QUESTION: Are there any suggestions on how to feed it (perhaps at
point C)?

What about, for example, substituting rope for the BCD wire (to maintain
the proper tension in AB and DE), connecting a coax to point B, another
to point C, then bringing both to a common point somewhere above ground
level (the shack is in the basement), and then connect them with a T to
the coax that goes through the wall to the rig? Should these two coaxes
be of any particular length?

NOT a dumb question. I was always under the impression that radiation
from the two parallel wires in ladderline was supposed to cancel itself
out... ergo no radiation. That's why they call it a balanced feedling.

I would like to ''do this'' because I lack tower space, at present.. I have a TV antenna that is on a small tower at about 28' , with a tv rotor. I also have a 6 meter horz ground plane , (you know the one that looks like a 'pie slice') I would like to add this horz gd plane to the tower,,,,,,,,, my question is this,,, would I be better off putting it on top of the Tv antenna or below?, what would be a 'good spacing' one way or the other (6 on top or 6 below)
I would like to get some use out of the 6 now, because it will be a while before I get another tower up. $$$
Thanks in advance. cl 73

Ed, your unstated assumptions is critical to the correctness of your
statement.

At sufficient distance from the parallel line, the fields from each
conductor are canceling providing the currents in each conductor are
exactly equal in magnitude and exactly opposite in phase. Under those
conditions, the parallel line is also balanced feed line.

Achieving those conditions (or a sufficient approximation) doesn't
happen automatically in the real world. There are all manner of things
in practical applications that would cause unbalance in the currents
in the conductors.

If the currents are not balanced, the fields will not cancel, and
there will be radiation to some extent, so the feed line does indeed
become part of the radiating system to some extent. Conversely, feed
line capture would contribute to some extent to received energy.

Owen

This is beginning to remind me of a panel I was involved with about 15 or so years ago when I was on an ad hoc White House Advisory Committee which was discussing the broadcasting of television to Castro's Cuba. I was a DOD tech rep and a careerist (I am now retired). We met in the White House Situation Room, almost directly under the Oval Office. Virtually all the other folks on this committee were lawyers and all but me and two military (one was the Vice Chief of the Joint Staff) were political appointees. This project went forward and is known as TV Marti, despite warnings from the technical folks that it could be easily jammed should the Cubans decide that they did not wish their population to see it. (The Cuban Government did want their population to see it and they did jam it). Although I did not have a political role in this matter and I was not a decision maker, just an advisor, what we had was a bunch of politicos trying to legislate the Laws of Physics. The engineering folks put forth all the technical arguements why this project could not meet its goals (that the Cuban average Joe with a common TV set could see American propaganda at any time), but to satisfy an interest group (the Miami Cuban exiles) the project was done anyway. In my technical capacity I was asked how many weeks or month it would take to jam this signal and I said 30 seconds. I erred, the Cubans identified and jammed the signal in 29 seconds.

This summer, I was back in my hometown, a small town in the midwest (I now live near Washington DC) and the ham club to which I belonged as a kid was making improvements to their club station, located in a public building, under the guise of Homeland Security Anti-Terrorism, and funded in large part by that program. Now there are many reasons why the public officials might want a back-up emergency comms systems in this sparsely settled area, but I seriously doubt that terrorism was one of them. More power to the club for having the initiative to try to get these funds, but multiply this by every hamlet in the 3000+ counties in the US and you have what my history books called "pork." This program in the hinterland is draining off funding for areas where a terrorist incident is a very real threat, like here in Washington DC where it did indeed happen, at a building in which I once worked for a time.

Point made. The driving force behind this is doing so mostly unseen or at
least that is our best guesstimate. Now, I would disagree as to the ability

to pull this off, there is no really advanced technologies required however one in which we have a patent interest is absolutely necessary (confirmed by legal and technical).

The FCC will have to comply to all kinds of waivers and spectrum rights issues so there must be a political and governmental mandate to champion this project. If not, it's not worth much more than a discussion.

If ANY such is to be performed, for railroad equipment, it must be well thought out, and, further, must face multiple Federal Agencies, and at least one private one (A.A.R., The American Association of Railroads) The additional federal agencies are: Federal Railroad Administration, O.S.H.A., and others-- One must also be aware of the facts that MANY frequencies would have to be involved, because of safety concerns (much like airlines), against interference. (No, it is NOT just about Train to train/work crew, and Dispatcher communications that is involved. Other equipment that railroads use are: 1) Track Carriers, for Crossing grade signals, dragging equipment, high-wide load, hot box detectors, Broken Rail detection, not to mention some telephony communications, 2) Remote controlled helper engines (unmanned engines on the end of trains to push-assist, and brake), 3) "FREDS" ("Friggin Rear End Devices"), some of which provide telemetry to the engineer of brake pressure, status of tail light, ect.- the new generation is conversant -2 way, also capable of dumping the brake pressure (emergency brake application, via remote control) and, other options (control of Railroad Central Traffic Control, or CTC. Also, on ALL track circuits, in signaled territory, the use of Insulated Joints is mandated, by the Federal Railroad Administration and can cause derailments, and other problems if NOT adheared to!and, 4) G.P.S. equipment
As to the Engines, tho, they have considerable power, they supply unorthodox voltages (a typical engine uses 600 volt, circuits, and the electronics used on them is in the 68-72 volt range- further, the newer engines are A.C. , the older diesels were D.C.
In sum total, then, this isn't a job for sidewalk superintendents! ONE item the railroads is STILL looking for is a concensus, for a Run-Away vehicle (by their work crews), that would alert a track gang of that runaway comming at them, causing considerable injury! Sounds to me like you have a PAR Omniangle, not a ground plane. A (vertical)
ground plane antenna is commonly a 1/4 wave or 5/8 wave vertically polarized
antenna with 3 or 4 ground radials. The Omniangle is a horizontally
polarized omni antenna.
If this is the Omniangle keep it 4' or so away from the TV antenna. Expect
some TVI on low VHF channels.

>
==========

According to the map of North-west Italy, field strength readings at
distances up to 28 Km from the transmitter are 1 or 2 dB better with
the CFA than the previous 80 metre mast.

It doesn't say what the frequency is. But if the mast is 1/4-wave high
the frequency is 943 KHz. and propagation is via groundwave.

Assuming the same transmitter was in use, the data is consistent with
both antennas working not very far from 100% efficient.

This does not, of course, prove anything about Maxwell's 4th Equation.

Can anyone dig up the original claims made by the inventors?

Reg.

1871. Aluminum tubing?

Newsgroup: rec.radio.amateur.antenna

From: Allan Butler <ka0ies@hotmail.com>
Message-ID: <1128562179_21@isp.n>
Source record: 69418

Hello Everyone:

I have tried all the local metal suppliers and several in the Chicago area to get 6061-T6 aluminum tubing from in very specific sizes. I need to get two pieces of 1.00 inch OD with a wall thickness of 0.058 inch that are twelve feet long. I also need to get four pieces of 7/8 inch OD by 0.049 inch wall that are twelve feet long.

Nobody that I spoke with stocks these items. Some of the big name suppliers were down right nasty about me wanting this small quantity of pieces.

Where would one go to get these pieces that I need to get for some antenna projects that I want to build soon? And not pay an arm and a leg for the privilege of owning this rare and unobtainable material.

Try asking on rec.crafts.metalworking. I _think_ the one to go to is
http://www.metalexpress.net, but I've never ordered from there.

There's got to be scrap metal yards in Chicago, where you may be able to
find one or the other pieces.

If the sizes are truely oddball then you may be asking folks to order a
lot of something they'll never sell, or (heaven forbid) have made up.

1875. US Tower TX-472 Base question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-06 02:22:51 UTC
From: Sluggo <luser@AOL.com>
Message-ID: <rk59k1tcgu4p2kctj5h4khr706lb5q59nt@4ax.com>
Source record: 69422

I've got a TX-472; the problem is that at this QTH there is a
limestone hardpan at about 5' depth. The original engineering
drawing calls for a base of 4X4X7' deep. The latest drawing,
available in .pdf form from their website, now calls for
5X5X6.5'.

I'm hoping somebody here has run into a similar problem
and can provide dimensions; UST says their engineer
can draw it up, but for $300 or so. Needless to say, cheaper
or preferably is always better. I can afford to send 'em
the $ < I bought the tower used, it's not like they "owe" me>,
but if I *have to* spend the bucks, I might be inclined to
see if a local PE with the appropriate skills could do it,
just in case there ever were an issue with permitting, etc.,
although I definately don't think that will happen, no permits
req'd in this county for amateur towers below 200' at this time.

Thanks for any help you can offer.

73,
Sluggo

If each side of the dipole is bent asymmetrically, then very little imbalance in feeder currents is evident. Off center feeding a dipole does unbalance feedline current. A double extended zepp is a good example of an unbalanced feedline with significantly different currents in each leg. It would be interesting to see just how much power is actually radiated from the feedline of such an antenna.

Frank

Not true. The "double" means it is a balanced dipole.
An EDZ is simply a 1.25 WL center fed dipole. The
currents are supposed to be balanced.

Ok, so I used the wrong name. What I meant was an antenna fed at the end
with open wire line, with one side of the feedline unconnected. Is it
called a zepp?

Frank

Yep, Zepps and Extended Zepps are unbalanced antennas. When you
add the word "double" to a Zepp or Extended Zepp, it becomes
a balanced dipole.

Zepp is an end-fed 1/2WL, Extended Zepp is an end-fed 5/8 WL.
Double Zepp is a center-fed 1WL. EDZ is a center fed 1.25WL.

hi allan,

http://www.mcmaster.com great online catalog,
they got everything even the kitchen sinks !
they even have local pickup if there is one in your area
to save on the truck fees.

how about ebay, lots of tubing online,
I got some nice 6063 (higher corrosion resistance)
.5 od from a guy in california.

Problem will be the ship fees, 12' is by truck.

Got to be a local place that has it.

73 tube guy

Jim,

I don't recognize the name, but did you ever work out of the
SF GOB? I spent 30 years there myself.

FWIW, I also hear from Brijet occasionally. You probably know
her (wherever you worked) as she was in charge of CDC for some years.
I spent a decent amount of time down there troubleshooting problems on
the remote lines to the zone offices.

I generally go about this sort of project from a different approach.

First identify the parts that are difficult and address them first.

In this case, I would determine what materials are available to me at
a price, quality and location that I could live with. Then I would
plan around the materials.

You are more likely to find usable materials in smaller quantities
from fabricators than from distributors. Pricing can vary a lot with
aluminum because the scrap price is a long ways from junk.

People in the antenna business are a good start. Fabricators of
irrigation systems are another source.

The length of the tubing will have an effect on its price. 12 foot
lengths will cost more per foot than 8 foot lengths in many cases.
Sometimes 20 foot lengths will be the norm for some stock.

Sometimes it is worthwhile to buy a commercial product and modify it
to your needs!

Thanks, solid points. We have identified the FCC assigned to RR frequencies
and they are outside of the AM/FM bandwidth.

Thanks, Jim, not holding any breaths. This isn't an in-house project, it's a coordinated effort that has all the complications and need for input as you have pointed out. We are asked to be Tech Central of sorts.

Why do you say that?

Here's a "heads up" for you, Ken. There are over ten FedGov agencies,
several legal teams and the rail lines that are working with diligence on
this, and similar, projects with the full intent of attempting to pull this
off.

While you sit on the sidelines and nay-say.

If I had a dime for cheap comments like yours, I could fund this project
out of petty cash. So goes the nature of those who do and those who comment
about the doers.

Never down in Oakland/the CITY, worked in K.Falls for years,
started in Eugene, in '68. Finally moved here to Sparks, about
12 years ago. Yeh, remember Brigit- bet she doing better than
most - had Dave Stubbles in Roseville, until they laid him off
about 7 years ago then he went to makeing big $$$!!-- and the
two Mikes-- Rosemond - he back in Eugene, and Barnecascle- he
in Elko, NV- got a year until retirement! Guess Bob Hall
still retired in K.Falls, and Jim Haas also there (he took my
job when came to Sparks). All retired (except for the two mikes).
Think you Kaiser D ?? have fun-- Jim (A.J. Foster) NN7K

Hi Denton,

One rule of thumb I've seen is that the radius of the top hat is equal
to twice the height it replaces.

Of course this probably varies considerably with the number of spokes
and the proportion of the actual height to the equivalent height. What
gives me pause to wonder is that if you can support 3 drooping hat
wires, why can't you keep one going straight up? You already have a
48 footer, why do you want a 38 footer with a hat? To give it the
appearance of being 58 feet? Why not a 48 footer with 5 foot top hat?

Ari- The power of a locomotive can be converted but, there are
certain problems, like going downhill, not only are brakes applied
to the cars, but the diesels go into "Dynamic Breaking", a complicated
way to say "Let the driver wheels run the motor (as a generator), and
them dump their output to banks of RESISTORS!! Provides great breaking,
but lousey voltage regulation! The radios on these units are powered
by (as stated,) 72 Volts, tho the radios also work on 12 volts (which
was the standard in Cabooses). The main point tho, remains that there
are considerable electronics (the new G.E. A.C.engines , from what
I have been told, are computer operated)! and that anything that
interfers with other items causes considerable greif to the operation
of a railroad- even turning a relay upside down can cause a derailment!

>>They are STILL looking for such a foolproof device!
>
>
> What's the issue, this appears not to be a huge deal?

Well, Ari-- the big deal is (Primarily in mountainous country- even
a grade of .5 degree, is considered quite steep). Now, suppose a
Maintainence of Way employees (push car, Motor Car, Hi-Railer (a
pickup equipped for rail travel) accidentally get loose- these can
be doing considerable speed- several MILES later-- worse, these
dont trip the signals, and further, the work crews have the track
from the dispatcher, so these can sneak up on workers with fatal
consequences. A similar thing happened on the old Siskiyou line,
when the powers that be were testing one of the old style of
remote controlled helpers-, going down-hill, on 5 Mile /Hour track
they called the remote to go to dynamic brakeing- but it went to
8-throttle instead (full throttle)! When they got it to control,
that train was doing 20 MPH! Had a bunch of scared people on it!
as you can see, it is not for the faint of heart! I sure wouldn't have
wanted to be anywhere near that track-- would you ??
I know it looks simple, and most times it is, but it doesn't take
much for things to get out of control! Have fun -- Jim

1891. Cheap interface for your Icom

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-06 20:18:29 UTC
From: Fred W4JLE <w4jle@w4jle.com>
Message-ID: <fcb8$434586ec$97d558d8$29619@ALLTEL.NET>
Source record: 69288

I wanted to use Ham Radio Deluxe with my Icom radio. It requires an CI-V interface. Being the cheapskate that I am, I checked the internet for "roll your own" information.

What I found looked really familiar, turns out it is identical to an interface I built to program my Radio Shack Pro 95 scanner. Plugged it in and it worked just great.

This means you can purchase a RadioShack 20-289 cable for $24.99 and replace the high dollar CI-V if you choose not to build your own.

1892. How to model on EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-06 22:10:13 UTC
From: David <groups@orbitcoms.com>
Message-ID: <9hh1f.9103$U51.3133@news-server.bigpond.net.au>
Source record: 69290

Does anyone know how I can model a coaxial sleeve antenna
on EZNEC ?

I know how to enter a standard Vertical 1/2 wave but not sure how
to represent the coax going up through the tubing(sleeve) in the lower
portion.

Thanks in advance.

I meant it seemed not to be, on first look, a difficult technology to
implement. For example, why not a sped sensitive device that set off an
alarm (vocal, radio, other) that could be preset "on" in situations where
these runaways are not manned?

I don't mean to downplay the potential complications but, technically,
getting an appropriate alarm system on a runaway doesn't sound like high
end technology.

<abcarisilverstein@yahoo.comxyz> wrote:

I don't know the details on how it works, but it seems to me that a
broadening of something akin to the On-Star technology might be a
solution work examining. I do not know if an On-Star operator can talk
to an equipped vehicle at On-Stars initiative, but certainly we have
the start of a system with a two-way radio with a satellite comms
link.

Admittedly, at the momeny On-Star is considered a luxury add-on option
and is currently available only in GM cars (to the best of my
knowledge.) But 23 years ago, I wrote a paper to my DOD bosses which
said this system the Swedes were developing called cellular phone
might have to be looked into. I was doing this as part of a survey on
new technologies which could have an impact upon intelligence
production. [I got a response from some Dilbert-type pinhead boss that
said it would go nowhere BTW]. Given a few years and some
competition, the On-Star paradigm could be as ubiquitous as
cell-phones are today. Even 23 years ago, I never forsaw the
possibility of virtually every teenager having a cell phone or that
there would be ten of them in just my immediate family [Wife, myself,
two adult children and their families. Son and his wife have two
systems each plus a Nextel.]

If an On-Star device, would be true two way, with GPS tracking, with
either end of the link able to activate the system. One could
broadcast a message to every active unit, either universally, or,
based upon GPS tracking to every unit with prescribed geo coordinates.
There already exists a somewhat similar system to broadcast weather
alerts to a passive receiver, although not normally deployed in cars.
Boaters already can have a Digital Selective Calling VHF radio in
their boats by which a coast guard can issue warnings. Such a system
is being mandated in the UK by a phase in process (e.g. new radios
with the old paradigm cannot be marketed unless they have DSC.)

And horror of horrors, one could alway investigate Broadband over
Powerlines (BPL). Wouldn't that give us hams some gas.

Why not -- they can eavesdrop on a selected vehicle, as was
proven once when the cops asked them to do so to a vehicle involved in
a kidnap.

And now thwt I think of it, they can iniiate a conversation
when they detect an airbag deployment.

Myron Calhoun wrote:
"Wasn`t the design criteria something like "Make it 40 feet high, and feed it 40 feet off center."

The Windom was named for the amateur who described it in an article. It was a 1/2-wavelengrh at its lowest frequency of use. A single feed wire is connected at 0.34 X the length of the antenna, from one end.

The Windom works best over highly conductive earth using a versatile matching network to the transmitter.

The 1/3 length feedpoint from one end is about 1/6 the distance from the antenna`s centerpoint. 40 feet off center, makes the antenna 240 feet long. This is 1/2-WL at 146 meters. It is 12 meters high. This is 1/4-WL at 48 meters and
1/2-WL at 24 meters.

Best regards, Richard Harrison, KB5WZI

The issue of installing a proprietary receiving device inside automobiles,
mandated by federal action, is one that is being given serious
conversation. The one problem that appears to be an issue is the liability
one. It will be a matter of time that someone will sue saying that the
system scared them or distracted them and caused this or tat accident.

Is a quiet zone a place like Placentia Ca. which had, for the railroad,
become a manditory blow your full set of air horns long and loud right
next to the bedroom windows every time you pass by no matter what time
of day or night it is, and where the locals have passed an ordinance
that says they're sick and tired of it?

1913. Trapping my 80m Inverted L for 160?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-07 20:02:29 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <di6k8knrq1@news.netins.net>
Source record: 69310

I'm having great success with my 80m inverted L (45' up and 25 or so feet out), with 26 radials (now). (Hung off the side of my tower)

I had a thought for something to just "get me on" 160. Is there any reason I couldn't put an 80m trap (design freq, please?) at the end of the 80m horizontal wire and stretch it out for 160? I read the article on W8JI's site
about coaxial vs other traps. Since I'm not going for broke, but just want a quick and dirty solution, I was thinking about making a coaxial trap for 80m out of RG8/X coax (or I could buy some 58a/u) that I have laying around. Not running more than 500w, so this size coax should be fine.

My questions:

1. What freq should I "design" the trap for?

1a. The program referred to on W8JI's web site (trap design) has no entry for 8x, but manual values can be entered. Anyone have ready access to the parms for 8x that I
need to enter?

2. I assume the trap will detune the 80m section, making it longer. Any ideas for a starting point on how much to shorten it, or should I just cut and try?

3. Will there be any degradation on performance on 80m from adding the trap and wire extension to enable 160m?

4. Any suggested starting wire length after the trap to resonate 160 towards the lower (DX) part of the band?

I don't want to ruin the excellent performance I'm getting on 80m, no matter what I do, so if I can't do this without compromising 80m, I'll think about another alternative.

Thanks for any ideas you may have. I wan't to get this done before the snow flies!

Cecil, do you have some quantitative explanation / support for this?

The treatments that I have seen of transmission line tuners where different Zo lines are directly connected do not suggest corrections / tolerances of the type you imply.

(IIRC, Terman discusses a fringing capacitance as a means of allowing for a physical discontinuity.)

I am not asking whether or not field conditions (and V/I on the conductors) immediate to the discontinuity are not Zo of either of the lines, just where has the 2% of a wavelength come from?

I did that once to make a dual-band inverted L, and it worked fine (I
also used a coax-cable trap). I tuned the trap for 80m.

Here is another alternative to think about that might be even easier:
simply put up a second wire for 160m, and feed it in parallel with the
80m wire.

For a while I had up a 160m inverted L with a vertical part of about
75'. I had a 80m wire (full 1/4 wave) running parallel to the 160m, and
spaced about 3 feet away. At the base, they both connected to the
feedpoint. I used a beta match coil across the feedpoint to match
the 160 wire, which had little effect on the 80m swr. It worked
quite well on both bands.

Assuming you really are wanting information and are not being silly!

Generally speaking MF stations that want that kind of range in a average broadcast mode of operation (ie the people receiving it only have small portables/car radios etc rather than well tuned antenna arrays themselves) need to have something close to a 1/4 wave vertical in a very large paddock with an underground earth mat. You can use longer antennas and feed them as half waves etc but your dimensions become a problem.

A 1/4 wave on 999kHz is 150 metres or thereabout. Thats roughly how high a guyed lattice tower/structure you would need. The ground mat would probably need to be at least 15 metres out from the antenna base.

This is of course not cut and dry. Varying conditions and topography govern what kind of performance you will really get. Most MF stations also run quite a lot of RF power. Something you didnt specify.

You can of course make a loaded antenna of any length and suffer the loss of performance. I cant remember the figure off hand but something like a 97% loss of antenna effiency wouldnt be unrealistic if you used a 6 metre loaded vertical.

Probably your best "bang for buck" would be to float an antenna from a kite. There may be air regs to consider though.

If you really are trying to do this pls repost some more detail of what you are trying to achieve.

As I recall it came from someone on sci.physics.electromag.

But think about it. The surge impedance (Zo) is basically just the ratio of the capacitance per unit length to the inductance per unit length. Those quantities might vary a little bit from one place to another, but probably not by much. And there are undoubtedly end effects which locally pull the capacitance and inductance values away from the ideal. So the length really need only be long enough for the variations to average out and for the total values to become large enough to swamp the end effects.

I don't doubt there is a discontinuity that disturbs the fields and
V/I ratio.

What I am asking about is the basis for the 2% of wavelength factor.

If I use RG58C/U on 160m, I read that Cecil is suggesting that the V/I
ratio is significiantly different to Zo for 2% * 160m or 3.2m
(125")from the end of the cable, which seems large when the physical
distance between the inner and outer conductor is 0.001m (0.04").

I am looking for quantitative support for Cecil's 2%.

Definition of what you are all waffling about :

"The input impedance Zo applies only for the duration of time taken
for an echo to be received back from the point where the line
impedance Zo first changes to another value.".

Distance can be measured either in metres or, if you like, fractions
of a wavelength. Wavelength involves frequency which is rather
meaningless because time is already a variable but on a different
arbitrary scale.

Only Cecil could dream up a use for such an effect.

> lines, just where has the 2% of a wavelength come from?

As I remember it came from the spacing between conductors Vs wavelength.
The spacing between conductors is about 0.1 inches for RG-58. How many
times that value would you think it would take for a transmission line
to force its Z0 upon the signals? At 10 MHz, 2% of a wavelength (24 inches)
is about 250 times the spacing between conductors.

==========

Yes Cec, you've told us before. I read the thread. That newsgroup
has more highly-convincing old-wives than this one has. They are just
a little harder to detect.

2% of wavelength is meaningless unless you also state by how much
input impedance has diverged from Zo after a time T has elapsed.
Wavelength also implies a frequency but what THAT has to do with it is
anybody's guess. It merely adds to the confusion.

It seems different people have this conceptual model of "a transmission line forcing its Z0 upon the signals" in a gradual way, though differing propositions for the length of line that does not behave as predicted by Zo.

An extension of that thinking is in the proposition that I have seen that a Bird 43 cannot give valid readings unless there is at least a quarter wave of 50 ohm line on each side of itself. In this case, the magnitude of significantly affected line seems to be 25%, someone else's is 2%, can they both be correct?

It seems to me that apart from the region of the significant distortion of the fields local to some kind of discontinuity, that the fields further along the line at a distance from the discontinuity large compared to the dimension of the discontinuity (which will often be the conductor spacing) should be as constrained by the physical parameters of the line (V/I=Zo for each travelling wave).

In the case of the Bird 43, I suggest that if had, say, at 1MHz, 75 ohm line and a 75 ohm load on the load side, that the V/I raio for the travelling waves in the region of the sampling element would be so close to 50 ohms as to not materially affect the accuracy of measurements on the 50 ohms coupler section, irrespective of the fact that the sampling element has only 0.02% of a wavelength of 50 ohm line on its load side.

(For avoidance of doubt, nothing in the foregoing is to imply the Bird 43 would be directly measuring or indicating the conditions on the 75 ohm line.)

Although Loren Windom, W8ZG/W8GZ, wrote an article about the antenna for QST, he had nothing to do with its development, even though it has taken on his name. Loren was a student at Ohio State while Professors Everitt and Byrne were physics professors and Loren was one of their students. He trailed along with them during their experiments with the off-center fed dipole, wrote up the specifics, submitted his writing to QST, after which the hams started using that antenna. Because Windom's name was on the article as the author, the antenna became known as the Windom in ham circles.

Well, you know, it depends......

Optimally, one would like to have separate, independent antennas for each channel, the way we constructed the first CATV head ends up in the hills of Pennsylvania in the 1950s. But, then Scientific Atlanta and others designed LPD antennas which covered multiple channels coming from one general direction, and since tower space and loading was always a concern (don't forget multiple runs of low loss coax enter that equation also), multiple antennas gave way to fewer antennas and lots of signal processing down at the base of the tower. Some sites had racks and racks of gear.

If the requirement is to provide signals to only one TV, a switch could be a good choice. On the other hand, if the design is for a whole house, or apartment complex or commercial building signal distribution system, then it gets progressively more complicated. Since Svend didn't specify, one had to conclude that he had already considered and rejected the easy solutions.

1932. Suitable antenna for RF behind a vehicle

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-08 03:59:45 UTC
From: David <groups@orbitcoms.com>
Message-ID: <RuH1f.10251$U51.2061@news-server.bigpond.net.au>
Source record: 69229

I have an application that requires RF to be propagated for several hundred metres behind a vehicle at 433 MHz.

I am looking for ideas for an antenna that could be built into the metal enclosure that houses the electronics. (ie. A single square or round enclosure).

Ideally the field would fan out behind the vehicle and not have any side lobes. (Only want RF behind the vehicle).
I am not worried about vertical propagation, Mainly just parallel to the ground about 1.5m.

I am not sure if maybe I could get a corner reflector, patch antenna, PCB loop, parabola or slot antenna into a fairly small surface area (around 200mm x 200mm).

The transmit power is 25mW.

Any ideas much appreciated.

Thanks

Regards

David

I suggest that it is your models that may be choking. EZNEC uses the
NEC engine for caculations and NEC can do all the items you mention
above.

Hi Lee,

Use the old stand-by of the screwdriver antennas, a screwdriver motor.

However, I expect you want two speed - then try a variable speed
battery powered drill.

For fine resolution and high speed both, look into the world of
Stepper motors. You can even design for calibrated settings instead
of hunting - or rough position indicators.

Maybe the electromagnetics people have a useful way to visualize it...

Deep inside the coax, the electric field lines between the inner and outer of the coax are exactly at right-angles to the main axis. Where that is exactly true, you have a pure TE10 mode so it's also valid to assume that V/I is exactly equal to Zo.

Very close to the end of the coax, the electric field lines from the center conductor start to reach out and connect with whatever is out there beyond the end of the shield. Then you no longer have pure TE10 and can no longer assume that V/I=Zo.

Coming at it from the other direction, the question would be: how far into the coax must you go before the field lines become accurately at right-angles?

We can be sure that the field lines won't suddenly snap from being divergent to being accurately at right-angles, so what we're really asking is: how far before the field lines are near-enough at right angles to make V/I=Zo a good engineering approximation?

Intuitively, the diverging field lines only seem likely to occur within a few diameters of the end of the shield. Field lines always connect with highly conducting surfaces at right-angles, and they won't like to be sharply bent to run along the axis of the coax.

In other words, the effect would seem to be mainly a function of shield diameter D. Again intuitively, I can't see where wavelength would come into it, unless D itself is a significant fraction of the wavelength (which is normally never true, and even microwave engineers try to avoid

it).

Following this picture of diverging field lines, there should also be a secondary effect depending on how the inner and shield of the coax are connected to the circuit outside.

All of this suggests that it's impossible to give a single answer that would be valid for all cases (unless you choose a number that's so big, it can't fail to be correct... like "120 radials" :-)

However, none of this speculation is of any practical consequence. All practical experience indicates that if a line is so short that V/I is not quite equal to Zo, the impedance transformation along that line will be so small that the effect of any Zo error is lost in the noise.

Lots of model-making and robotics suppliers in the UK have small
plastic gearboxes, plastic shafts, couplers etc. Try some of the links
from my "Components and Suppliers" page.

As a short-cut, try to find a small battery-powered barbecue spit motor
at one of the home and leisure stores (probably in the end-of-season
bargain bin). They are still a bit fast, but will run at reduced voltage
or with pulse-width control to slow them down.

>gearing on my spare cap :-/

Hi Lee,

One way to control that, at least speed-wise, is to turn the DC
voltage into pulse-width modulated voltage. You are always applying
the same voltage, but you turn it on for a short-to-long time, and off
for a long-to-short time over any interval. You change the speed by
changing these times. This is more properly called Dwell Time.

This offers the prospects of maintaining a constant torque over a
considerable range of speed. I'm not certain by what you mean about
"too much torque," unless you have too much resistance for the gears
to drive.... Stepper motors are also noted for high torque - it goes
with the turf.

Source record: 69238

Re-reading Svend's mail, he wants Channels 22 to 37, 40 to 44, and 49 to 64 (Antenna 1). He then needs to add Channel 21 and 38 + 39 (Antenna 2). This should not be too difficult.

Obviously, the filters will not totally reject channels which are close (for example, the 22 to 37 filter will not reject 21 very well). There will be a certain amount of unwanted noise outside the passband of each filter, and ghosting (due to pick-up on the 'wrong' antenna) may not be totally eliminated. It may be necessary to fit one or two notch filters.

I would first fit a level-raising amplifier to the feed from each antenna. There is nothing like having lots of signal level to play with!

At the output of Amplifier 1, use a 4*-way CATV splitter to obtain four feeds. The loss will be about 8dB (for a splitter which uses ferrite transformers). Each output will be isolated from the others (typically by about 25dB).

[*Note: 2, 4 and 8-way splitters are 'standard building blocks' in the world of cable TV. You can get 3-way and 6-way, but they are not easy to find).

To three of the feeds, fit bandpass filter for Channels 22 to 37, 40 to 44 and 49 to 64. He can use the fourth output for monitoring.

At the output of Amplifier 2, use another 4*-way CATV splitter to obtain 4 feeds. To two of the feeds, fit bandpass filter for Channels 21 and 38+39.

He now has six separate TV feeds. If he wants, he can fit in-line variable attenuators to each to equalise the signal levels.

The six TV feeds are then connected together using an 8*-way splitter (as a combiner) or two 4-ways then a 2-way. There should be little interaction between them. The loss will be about 11dB.

Assuming a loss of 2dB for each filter, the total loss of this system will be 8 + 11 + 2 = 21dB.

All that remains it to design (or obtain). 'normal' filters for each block of channels. There is a company in the UK which has a good range of equipment for MATV and CATV:
http://www.taylorbros.co.uk
I don't see anything there which is exactly what Svend wants, but here probably other companies in Europe which have can supply similar equipment.

Ian.

Assuming it is a permag motor, reduce the motor voltage... add a
current limited driver to limit the torque, an electronic shear pin if
you like... except it doesn't shear.

I am assuming that you are trying to tune the reactance out, to
achieve an acceptable VSWR on the line to the ATU/transceiver. Have
you considered automating the capacitor drive. You could build a phase
detector (between V and I at the antenna input) as a sensor to control
the motor drive.

Here in the USA ALL Electronics had 12volt 6RPM DC motors. I drive my large 4600v variable with it using a DC pulse width motor speed control. The motor control was around $22 as a kit in the USA. I would actually like about 3RPM since the motor control slow speed needed for fine tuning is in a small range. I could gear it but a mechanical mess. A simple DPDT switch is used to reverse direction.

Check your electronic parts dealers to see if they have motor with built-in gear boxes. Best way to do it.

Dick N3HKN
PS: My loop is 1 meter on a side square and is used on 20 meters in the attic. I have set it outside where the noise level is less but on really cold days the motor will not turn. Used a simple plastic container from a local discount store. I'll stick to the attic since I have a GAP vertical as well. Yes, they are comparable given the dipole like pattern of the loop.

then please take it back there. it makes no sense as it would force the effect to get longer and longer at lower frequencies. the more logical effect is fringing effects from edges of the shield if it isn't properly connected to a proper termination... this is something that i can measure with my tdr, and it is definately a very short range effect. just think, if i pulse a line with a 1khz square wave and the effect got longer with lower frequency what would the return pulse look like?

Yes, i`ve been looking into that and it seems the best way to go, a local
supplier has a panel mount version in stock £15.00 ($16.00??).....so!!.

Not enough resistance, the capacitor comes to the end of its travel but the
torque wants to continue..... hence the damage to my spare capacitor!!!.

Just model a vertical dipole. The presence of a coaxial cable, within the lower conductor, will not effect its performance. For your model both upper and lower conductors should be the same diameter. Dissimilar diameters in a model can produce erroneous results.

NEC has its limitations, but alternative, FEM based, programs can cost tens of thousands of dollars.

Frank

Planning on putting up my own tower and I need a safety harness/working belt of my own. I have used some on other projects so I have an idea of what I want, just need a few web sights/brand names to look for. I don't need a super heavy duty one to work in all day,every day, but one to use two or three times a year.

I've modeled ground planes with bent radials and J antennas
using EZNEC and got reasonable results. Never tried a patch.
EZNEC's limitations are well known and well documented so
knowledgeable users can avoid those pitfalls. Of course,
nothing is foolproof.

I think if you will recheck that posting you will find the assertion
was that a Bird 43 cannot give valid readings by sampling at a point.
The line must be at least 1/4WL, and preferably 1/2WL, so that voltage
maximums and minimums will exist and can be measured.

And that 2% of a wavelength is from my faulty memory. I'll try to
Google and find the exact quotation.

Apparently, the 2% of a wavelength that I was remembering was
at 10 MHz. 1'/(98.4*0.66) rounded to 2%. All I was interested
in at the time was proving to Reg that one foot of coax forces
Vfor/Ifor = Vref/Iref = Z0, the boundary conditions assumed
by Bird Wattmeter designers. Since Kevin was not familiar with
PL-239's, I erred on the side of caution with the 2% estimate.

>It addresses it adequately but doesn't answer any particulars.
>Given PL-239 connectors and RG-213 coax, I wonder what the
>answer would be for 10 MHz?

I'm not familiar with the connectors in question. Assuming
they are properly attached, they should not introduce much
mode diversion. For 10 MHz I would expect that all other modes
would be non-propagating (i.e., evanescent) even though RG-213
is a large coax (improved RG-8 apparently). The speed of propagation
is listed as 66%, so the nominal wavelength is 3/2 times the free
space wavelength for the TEM mode. 3/2 x 30m = 45m, which implies
the decay rate in space for non-TEM modes is going to be large
as the cable diameter is .405" (jacket) which implies the
spacing from inner to outer conductors will be less than .203".
For order of magnitude estimate, assuming the lowest non-TEM mode
can be approximated using a characteristic equation that really
is only applicable in Cartesian geometries:
(1/45m)**2 = (1/.203")**2 + kz**2
Clearly, kz must be imaginary to make this work. thus an
evanescant, non-propagating wave:
kz**2 = (1/45m)**2 - (1/.203")**2
To the accuracy used to date, the first term on the right
is negligible, so the decay rate, alpha, can be estimated:
alpha**2 = - (kz)**2 = (1/2.03")**2
Or, the lowest order undesired mode should reduce intensity
by a factor of 1/e (0.37) in about 2.03"; power will reduce
by that factor squared in the same distance (.135). In

about four inches, undesired mode power is down to about
0.018, in six inches, .00248, and after a foot, 6.14x10-6

You should double check my algebra, but I think the estimate
is reasonable. To put it into other terms, since the wavelength
in the coax dielectric is 45m and the conductor to conductor
spacing is about 2", any non-TEM mode will suffer attenuation
in E-field intensity with a space-rate constant rounghly
equal to the conductor to conductor spacing. INtensity
drops by 1/e = 1/2.71828 every 2 inches. Power availalbe
drops faster, being square of intensity.

So unless almost all the power diverts into an undesireable
mode (by a factor of more than a million to one), one foot
of cable should see pure TEM at the end.

HTH
Kevin

Hi Lee

Two thoughts

Re stepper motors. You can often find them in old junked scanners. A nice cheap source. If you are feeling really cheap the interface can intially be a simple TTL counter cct and some pass transistors. I once used one off my PC parallel port for an EzAl antenna system.

Also look at the possibility of using a piston capacitor and driving that with a threaded bar connected to your motor. This may still be a little fast though. You might also get away with a long lever and threaded bar arrangement if turning a standard rotary capacitor. Kind of limits you to something less than 180 degrees tho.

A car windscreen wiper motor is another possibility also through a threaded bar. (Overkill on the torque tho)

Cecil was quoting someone else there, and is completely innocent :-)

Here's how the Bird 43 measures VSWR. It contains a pair of needle-fine voltage probes, powered by small explosive charges. When coax is connected at either side, it fires those probes out into the coax until it finds a voltage maximum and a voltage minimum. Then it computes the Voltage Standing Wave Ratio and a recoil mechanism reels the probes back in. It's so slick, it all happens before you even know it.

Warning: when handling a Bird 43, keep all sensitive parts more than 1/2WL from those sockets!

An alternative possibility is that the Bird 43 does give valid readings by sampling at the point where it physically is.

Thanks for the URL. I did not mean I wanted to skimp on the quality or
safety. I spent about half a day several years ago in a demonstration at
work on safety harnesses. They were for fall protection only and not for
working in where you want support and both hands free like you would on a
tower. I just ment that I will only use it for a short period of time and
not very many times per year. What I would be skimping on would be heavy
padding and comfort. Sort of like you can sit on a wooden chair for a short
period of time but if you had to sit all day every day you would want to
spend lots more and get a good padded chair.

Understood. The one that I liked to has side D-rings so you can use
it similar to a lineman's belt. I confess to near terror when I'm
first on the tower, which partially subsides after a while. I use
both a belt and suspenders approach with a safety rope and carbiner
clipped to the chest ring and the tower while ascending or descending
and a standard belt to the waist rings for two-hand work.

There is another safety issue that you can read about here:

http://www.cdc.gov/elcosh/docs/d0500/d000568/d000568.html

I live in a semi-rural area with a fire department station about three
miles away, but with a small staff. I sent a copy of this paper to
them with some remarks that I did climb on occassion and if they had
to rescue me, they should be aware of these issues. A paramedic
called me and told me that this was all very interesting, but they
wouldn't get to me in time to save me anyway, so not to worry :-).

>>Just model a vertical dipole. The presence of a coaxial cable, within the
>>lower conductor, will not effect its performance.
>
> But the presence of the coax below the antenna sure will.

As an experiment I modeled a #14 AWG, 133 segment,134 ft free space dipole. The input impedance at 3.575 MHz is 74.01 - j 0.749 ohms. Adding an additional 25 ft wire at one end -- ends separated by 1.2" -- the input impedance becomes 74.155 - j1.97 ohms. There is no discernable effect on the radiation pattern.

While this test is not precisely equivalent; the presence of a, non connected, axial extension appears to have only a minimal effect on the antenna parameters.

Regards,

Frank

1971. Re: Suitable antenna for RF behind a vehicle

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-08 16:31:47 UTC

Message-ID: <ks8l13-p4t.ln1@p400bob.personal.cox.net>
Source record: 69274

Hi David

There are lots of possibilities here. Generally speaking though confining the antenna to a metal enclosure of 200mm x 200mm is going to severely impact its efficiency. I'd suggest that if you really want to use this size constraint make part of it out of something transparent to the signal (eg plastic/fibreglass)

My first thought (and there are bound to be many more) is to setup a single full wave circular loop fed through a 1/4 wavelength balun such that the shield on the opposite side of the loop from the feedpoint is "grounded" there. Then mount it in front of a metal plate of gauze inside the plastic thing that contains it. If it is a square shaped box make it a square full wave (quad) shape. For horiz polarization the antenna would be fed at top or bottom of loop.

Assuming the TX/RX device needs a 50 ohm antenna you can then adjust the loop to plate/gauze distance to get the best match or received field strength.

You could of course mount the antenna off the metal box face some, and maybe use plastic of the same metal box dimensions if it is important to keep it enclosed.

My gut feel for approximate dimensions are as follows;

Antenna to metal plate/gauze - 50-100mm

Antenna diameter (if circular) - 200-240 mm

Antenna side length (if square) - 170-190 mm

This antenna would probably give you a large single horiz lobe in the vicinty of 120 degrees half power beamwidth. This vertical pattern will of course be affected by the nearby ground and much of our radiation will be angled upwards and broken into a few lobes.

If the 200mm is a hard dimension number I'd suggest you consider lightly loading the loop with some inductance to make it smaller. This will of course impact performance. I still maintain though that it should be mounted clear of the metal box in plastic or air.

Keep in mind that at 433MHz there is going to be a lot of multipathing and the phase cancellations may be an issue if the distance becomes too great. I havent bothred to figure the path loss for the circuit you have described. It might be worth doing so to make sure its doable. Another consideration is do you expect it to work over the several hundred metres if there is a hill in the way?

Hope you find this useful.

Cheers Bob VK2YQA

At work we have a short meeting every morning and I did a talk on this very issue about 6 months ago. I did see where some company was making some straps you could lower and stand on the straps if you did get hung up in the air. We don't do much climbing but anything over 6 feet off the floor that is not an aproved structure we have to wear a safety harness. I don't do that much but do wear one about once a month. Even going up a ladder where your feet are over 6 feet off the floor we have to wear the harness.

What I think I was really fishing for was more of a working/positioning harness and what the hams that have towers are using. Maybe a double duty one that is mainly a working harness like a linesman belt but the full harness to also act as a safety harness. The full body ones we have at work are just for safety and do not have the D rings at the sides near the hips where you can put a working belt.

Automatic Level Control, ALC.

What characteristics of the load impedance are used to automatically
control the drive-level of the power amplifier?

Whatever they are must apply to CW, SSB and FM modes of operation.

Reg.

Cecil, it is someone else who has on a number of occasions suggested
the quarter wave thing in email correspondence, and here in postings.

My suggestion is that the sampler inside a Bird 43 coupler section is
sufficiently far inside the 50 ohm coupler line to provide
measurements within the instrument's stated accuracy of what is
happening within the 50 ohm coupler, irrespective of whether, for
instance, a 75 ohm line is attached to the coupler on the load side.

The measurements of what is happening within the Bird 43 coupler could
then be used to model what is happening on the adjacent line, having
regard for any Zo changes, loss, length etc.

Yep, it's not me, it's Reg. I have defended the Bird wattmeter
design. Reg sez one needs at least 1/4WL and preferably 1/2WL
in order to accurately ascertain the "real" SWR.

Will you be working alone? Who might rescue you, and how long might it
take?

If you plan on "hanging around", plan to be comfortable. Adequate
width of leg straps in case you are sitting for a bit, clearance for
the family jewels (assuming you are male, adequate width in the back
to be comfortable leaning back on a pole strap.

In my experience, lightweight harness are strong enough for the job,
they just aren't comfortable. They are for fall arresting, instant
rescue. What is suitable for hauling a plumber out of a sewer might
not be comfortable on a tower for hours (even once a year).

For pole straps, my preference is for adjustable ones that allow you
to set a convenient position for working to minimise fatigue from
using an arm to hang on. Pole straps are not fall arrestors, if you
want a fall arrestor, you also need something like a shock absorbing
lanyard.

Not it was not Reg... end of the guessing game.

Having regard to the definition of VSWR (SWR), I can understand Reg's point that the direct way to measure VSWR requires sampling voltage or current over a quarter wave of line where you can find / observe the actual minimum and maximum.

Having said that, there are other measurements that one can make that allow one to reasonably predict what the VSWR would be.

Call me thick, I still don't understand why you can't sample the RF V
and I and feed them to a phase detector to provide an indication of
whether to adjust the capacitor up or down to achieve resonance (V in
phase with I).

Hi Owen, Of course you can sample the RF-V and I and use it to
adjust the capacitor via the motor control circuits. The motor driving
voltage is DC, and I don't understand the inferences in this example.
Automatic antenna tuners work on this principle, and work well.

>What characteristics of the load impedance are used to automatically
>control the drive-level of the power amplifier?

Well, as you no doubt know Reg, in the early days of application of ALC to amateur transmitters it was literally to control the drive level of the PA, and often did that is a closed loop where excess drive in a class AB1 PA was detected by occurrence of grid current, which was used to reduce gain in prior stages to limit the drive level to AB1 conditions. Such a control system is indirectly affected by the PA load.

Today, modern transceivers have further developed that idea to controlling the RF output voltage or (differently) PEP power out (ie be detecting Vout or power out and adjusting gain in prior stages to limit output. This might more loosely be called Automatic Power Control. In this case, the measurement point of the control loop is more directly affected by the load.

Many modern solid state transceivers also detect poor loading using a reflectometer calibrated for the specified load for rated output power, and reduce drive based on the measured "reflected power" in the reflectometer to protect the PA (if that needs to be done anymore for that purpose - transistors are more robust). This might be properly described as PA Protection. The measurement is directly affected by the load, and is highly responsive to load changes beyond a configured threshold.

All of these things may be included in the readers understanding of ALC. Certainly, many if not most, modern solid state transceivers perform all three of these functions, and display the control voltage as "ALC". And many current model external valve based high power PAs (Linear Amplifiers) still use the grid current detection scheme (if it is hooked back to the transceiver).

>

Either will worK OK. The main point is to get the three base pins in the correct position and vertical. The original TX-472 came with a plywood template with a hole for each pin. Place that on the wood surrounding the hole. My last hole was close to 4 X 4 X 7.

If you don't have the 36 inch base pins with the bottom in a L (total length is 42") you have two choices. You can get a new set from US Tower (try to het HRO to order for you) or get 1" galvanized universal bolt (probably have to order from a hardware store or Mcmaster-carr) and have the bottom 6" bent at a right angle.

I have moved my tower 4 times and have had good luck with the universal bolt.

Two mail order places to try: OnlineMetals.com (I've gotten great
service from them being only a few hundred miles away) and Aircraft
Spruce (never ordered metal from them, but lots of homebuilders do).

Mouser has non-Greenlee punches much cheaper than the Greenlees. I've
got some and they're fine. There might be a difference in a heavy-use
setting, but probably not for typical homebrewing.

==========

Automatic Antenna Tuners and Magloops.

All ATUs work on the principle of adjusting tuning components such that the load presented to the transmitter has a reflection coefficient of RC = 0+j0 ohms. When mismatched the RC has both magnitude and phase.

So there must be two L and/or C variables. That's why there are always at least two knobs on the front of a manual tuner. Or, when automatic, two electric motors. Or a set of relays which accomplish the same tasks.

In the case of a T-network the variable components are usually a pair of reversible motor-driven capacitors.

There is always a reflexion coefficient bridge which is at balance when the transmitter load is simultaneously R = 50 and jX = 0. Or impedance Magnitude = 50 and Phase = zero.

The RC bridge circuit is similar to the so-called SWR bridge except that there are TWO voltage outputs - proportional to magnitude and phase of the RC. Output voltages are amplified to drive the reversible capacitor motors or operate the set of relays. The motors go backwards and forwards and react with each other similar to what a human operator does. When Z Magnitude = 50 and Phase Angle = zero, or sufficiently near, motors stop and the green LED comes on.

Now, in the case of a magloop there is only one variable - the tuning capacitor. The other component involved with the tune-up process is FIXED. It is the diameter of the small coupling loop inside the main loop which is fixed.

The small coupling loop, in conjunction with the main loop, behaves as the single-turn primary winding of an impedance matching transformer.

The main loop, when at resonance, has a very low purely resistive impedance, the sum of the radiation and loss resistances.

The effective turns-ratio of the transformer is approximately proportional to the ratio of the areas enclosed by the two loops. It so happens that when the diameter of the coupling loop is approx 1/5th of the main loop diameter, the impedance looking into the coupling loop is 50 ohms. If a 75-ohm feedline is used then the coupling loop needs to be a little larger.

A nice property of a magloop is that an impedance match is approximately independent of frequency. When changing bands it is not necessary to change the diameter of the coupling loop even if could easily be adjusted.

It can now be seen why the conventional ATU cannot be used with magloops. What is needed is something which searches for minimum loop impedance, or zero phase angle, as the tuning capacitor is varied. It then stops.

Any ideas?

Reg, G4FGQ

Isn't that what I described, a control system that samples RF V and I
at the antenna end of the transmission line, and uses that to control
the direction of the capacitor drive motor to send it to the point
where the phase difference is zero?

Yes, I am aware that is only adjusting the reactance of the load
presented, but yes, I was aware the R component doesn't vary over a
very wide range over the loop's operating frequency range, and that if
X was tamed, the line losses would be acceptable.

> 73's
> Richard Clark, KB7QHC

Hi Richard,

Axial extension 1.2" from antenna end -- Results as follows:

Extension Length (ft) Resonant Freq. (MHz)

0 3.5765
5 3.576
10 3.575
20 3.574
50 3.5725
100 3.5720

For a total shift of 4.5 kHz (0.125%) from zero to 100 ft

73,

Frank

Yes, good idea......i`ll look into that.

> I am assuming that you are trying to tune the reactance out, to
>>>>>> achieve an acceptable VSWR on the line to the ATU/transceiver<<<<

An ATU does not work too well with a magloop as the magloop has its own
tuning capacitor (ATU) built in all that happens is that the antenna and
feed are tuned as one....unless i misunderstand your comment!!!.

. Have
> you considered automating the capacitor drive. You could build a phase

There was an article in RadCom some years ago describing an auto-tuning Top Band vertical, which used a simple inline phase detector and a little DC tuning motor. The phase detector is nothing complicated - it's very like a toroid-type SWR bridge rearranged components - but there was a lot of practical information about what's necessary for RF shielding and decoupling.

The whole thing should work equally well for a magloop, since the electronics don't care what kind of antenna it actually is.

The article was by Tim Forrester, G4WIM, and was reprinted in G4LQI's 'HF Antenna Collection' book... my copy of which is unfortunately in another country.

Ian,

A magloop is an altogether different kettle of fish to a top-band vertical. For a start, the Q of a magloop is in the order of 1000. For a top-band vertical it may be about 50. For most antennas it is about 10.

What I would like to know is has anybody ever made an automatic tuner which works with a magloop. Or has manufactured one for sale?

By the way, thanks for the Teslar papers although I am unable to run the programs.

Reg.

Not fundamentally different - it only means the magloop tuning will be
more sensitive. The servo will still try to drive the system to
resonance at zero phase angle.

The overall gain around the servo loop will be the product of the
antenna Q, the mechanical gear ratios and the voltage gain in the
electronics. The last of these can be adjusted with a single pot. If you
have a higher antenna Q, you simply need less voltage gain.

Don't know, never looked.

>By the way, thanks for the Teslar papers although I am unable to run
>the programs.

(I only downloaded the program for coupled inductors, but haven't
studied it yet. It ran OK, after having extracted all of its files into
a real directory; it won't run from inside the .zip 'directory'.)

my plan would be to construct a 2m beam, then construct a 70cm beam, and
just mount them near each other.

Let me expand on this. If---big if---the sleeve is the correct length
and lossless, so that it acts as a quarter-wave choke, then in theory
it does decouple the coax from the radiator.

A few points however:

1. The Vp of the choke will depend on the effective dielectric
constant of the air/outer jacket combination. The choke so formed
will likely be fairly lossy as the outer jacket is probably not the
lowest loss dielectric around.

2. Since the choke Vp will be lower than an air-dielectric one, it
must be physically shortened to optimize the choking function. This
combined with the usual diameter differences between the sleeve and
the upper radiator (rod) makes the vertical dipole asymmetric, i.e.
unbalanced, when the rod length is adjusted for resonance. In effect
the feedpoint is moving up and down as the rod length is adjusted. In
practice, this is no big deal but offered for completeness.

3. You can model this antenna to some extent. Below are some
coordinates for a model I used. The wire size was #12, all lengths in
inches and the frequency was 100 MHz. I used Multinec invoking EZNEC 4
for the calculations. In Multinec I made the Z a variable and could
vary the height above ground programmatically. The sleeve is

represented by four stubs; more would perhaps more accurately
represent a cylinder, but I don't believe it's necessary. Since the
"coax" connects to ground, MiniNEC ground (avg) was used. To observe
NEC limitations, all segments are (very nearly) the same length and
adjacent segments are aligned. The sleeve length was adjusted to
minimize the current on the "coax" below the antenna (wire #4) and the
rod length adjusted for zero reactance.

```
End 1 End 2
X Y Z X Y Z Dia Segs.

Source wire
0.00 0.00 354.09 0.00 0.00 355.09 #12 1

Upper radiator (rod)
0.00 0.00 355.09 0.00 0.00 382.47 #12 29

"Coax" inside sleeve
0.00 0.00 326.84 0.00 0.00 354.09 #12 29

"Coax" below sleeve
0.00 0.00 0.00 0.00 0.00 326.84 #12 337

Top of sleeve
0.00 0.00 354.09 0.00 2.00 354.09 #12 2
0.00 0.00 354.09 0.00 -2.00 354.09 #12 2
0.00 0.00 354.09 2.00 0.00 354.09 #12 2
0.00 0.00 354.09 -2.00 0.00 354.09 #12 2

Sides of sleeve
0.00 2.00 326.84 0.00 2.00 354.09 #12 29
0.00 -2.00 326.84 0.00 -2.00 354.09 #12 29
2.00 0.00 326.84 2.00 0.00 354.09 #12 29
-2.00 0.00 326.84 -2.00 0.00 354.09 #12 29
```

4. If SWR is your criteria for "goodness", you will be in for a big
surprise. The above example places the midpoint of the antenna at 3
wavelengths above ground. The feedpoint Z is a nice 56.6 +j0 but the
elevation for maximum radiation is 71 degrees above the horizon. If
satellite work is your goal, this is your antenna.

5. Despite the "choke", the transmission line is part of the antenna.
Skeptics of the model above can remove the sleeve and put a trap at
end 2 of the coax and see similar results.

Hi Frank,

Thanx.

Was this for a coaxial line running from the drivepoint, then parallel
to the lower leg, down? Was the parallel separation 1.2" as you
describe above?

Was this line modeled as a third wire connected at the drivepoint and
dropping as I describe?

> Not fundamentally different - it only means the magloop tuning will
be
> more sensitive. The servo will still try to drive the system to
> resonance at zero phase angle.
==========

Ian, what slightly worries me is -

(1) The resistive component of antenna input impedance, as measured at the input of the small coupling loop, when the main loop is even only slightly off-resonant, is altogether different from 50 ohms but is not included in the bridge balancing process. The diameter of the coupling loop is fixed. Yet magnitude and phase adjustments react upon each other as is experienced by a human operator with two variable controls.

(2) The coupling between the two loops is very loose. We are trying to adjust the main loop exactly to resonance via a means which is very insensitive to its resonant condition. Direct voltage and current sampling connections to the main loop itself are impossible.

(3) We can imagine a situation where the impedance phase-angle is zero at the measuremnt point, and the green LEDs light up, but which does not correspond to exact resonance in the main loop. And exact resonance matters with a magloop.

(4) Because the system is trying to reduce a phase angle to zero in the presence of two unknowns, instability can result. We can imagine the system continuously hopping about trying to find the zero.

As you can see, I have difficulty in describing what I think happens circuitwise. But I shall be convinced only when somebody produces something which WORKS reliably without human intervention.

It may be possible but where is it?

Regards, Reg, G4FGQ

Thanks for the information on where to find aluminum for antenna projects.

The idea of scrap yards would not be a bad one except one does not know what the alloy or temper is on the aluminum. If it isn't right, the first good wind would end up making a nice bundle to go back to the scrap yard. :-(

The commercial locations that were given in the information are helpful. Even the Texas Towers site referring to a different alloy is a help. Now I can go back to the locals with a request for the different alloy and see if they have any of that in stock.

Again, thanks everyone for the pertinent information.

As for the spelling changes. I am an American. I do not speak English, I speak American. If I had put the English spelling on the tests that I took in school I would have failed. I put the American spelling on the tests and at least passed the tests. Schools don't like it when one tries to be a unique individual.

Find out who changed the spelling in the past and point your blame thrower at them.

Basically it boils down to this is the way we were taught to spell and speak.

Maybe we really don't speak English after all these years. We may speak and write a totally different language of American that is based on the English language.

If that is the case then there might be reason to believe the same thing is happening with Australia, South Africa and a few other parts of the world.

As an example of this get someone from Australia and listen to them. Even better hold a conversation with them. Then find someone from South Africa and converse with them on something in a totally different setting. After talking to both of them one on one, get them both into the same room and introduce them to each other than get them talking to each other about anything you want. You will find that the two dialects are different.

OK I know. It's Off Topic. :-) But I started the topic so I can twist it. Right?

Again folks, thanks for the information and it will be very helpful.

Bye, Cheerio, G'Day, Seeya, Talk ta All Yall Later. :-)

Ian White, G/GM3SEK wrote:
"An alternative possibility is that the Bird 43 does give valid readings by sampling at the point where it physically is."

Bird claims + or - 5% of Full Scale accuracy for the Model 43.

Why is there power from the reverse direction for a Bird Model 43 to indicate? There is no second generator sending power in the peverse direction. The reverse r-f comes from a reflection. The coax enforces a voltage to current ratio equal to Zo in each direction of flow. Zo is 50 ohms in the Model 43.

Reflection does a peculiar thing. It produces a 180-degree phase reversal between a wave`s voltage and current. Bird uses the fact that the current is in-phase with the voltage in one direction of travel and out-of-phase in the opposite direction of travel to distinguish between the two directions.

To distinguish, Bird takes a voltage sample and a current sample at the same point in a 50 ohm line. These two samples are scaled and calibrated to produce identical deflections of the power indicator.

Out-of-phase samples thus cancel leaving the in-phase samples to produce double the deflection either would produce alone. This deflection is carefully calibrated in watts.

Reversing the direction of the wattmeter element, reverses the sense of the direction indicated and reverses the direction in which the samples of voltage and current cancel.

The Bird has been satisfactory for about a half century.

Best regards, Richard Harrison, KB5WZI

Owen wrote:
"---I can understand Reg`s point that the direct way to measure VSWR requires sampling voltage or current over a quarter wave of line where you can find / observe the actual minimum and maximum."

Yes, and the direct way to measure MPH would be to measure the number of miles and divide by the number of hours to get an average value. It`s not often done that way. Maybe about as often as people find maxima and minima on a transmission line and compute their ratio.

It is more convenient and sufficiently accurate to use indirect methods for MPH and SWR.

Best regards, Richard Harrison, KB5WZI

Reg, G4FGQ wrote:
"It may be possible but where is it?"

In the shortwave broadcast plant I worked in 50 years ago we had a 3.5 KW AM Raytheon "Autotune" transmitter we used to talk back to our program relay transmitting station in another country. We called it our "order-wire " transmitter. It or its twin were sometimes used for broadcasting but it was low in power for that job.

This autotune transmitter had a rotary telephone dial on its panel for programming its mode, operating drequency, etc. You could instruct it to listen to instructions, then dial in A-3 for AM, followed by the frequency you wanted it to operate on, such as 15,925, hit the go button, then stand back and watch the knobs spin as it tuned itself up completely. including putting the desired power into a dummy load. A ready lamp informed you it was good to go on the air at the push of a button. It worked like a charm.

Collins made autotune transmitters which are now military relics of WW-2. I never toyed with one of those.

It may be a fine project which will produce the goods, but let's look at the way you've brought it here:
- you wanted help to get up a truck-mounted transmitted to over-ride all AM/FM communications in an area. You wanted to drive the truck at up to 70mph through a disaster/emergency area, for no adequately explained reason (the RF is going for a mile or two outside the area, so why drive the truck?). You got told why it's impractical as described.
- you suddenly changed it to a loco mounted project. You struck gold on this one as there are people here who clearly have industry experience. You're not poo-poo'ing their skepticism, but certainly not fazed (may not be a bad thing....). Why not pour the funds into controlling all these uncontrolled level crossings instead of producing a 'box' to go on every loco that may drive through the US?
- you are trying to get commercial advice in a Ham group - is this the right venue?? I'd have thought not, though it's certainly cheap.

- having ten agencies etc etc on your side may get the project through, but is it the right solution to whichever problem it's attacking?
- 'nay-sayers' are a pain-in-the-arse, agreed - no-one likes them! - but sometimes you need to hear the other side.

Cheers.

Ken

"Owen Duffy" wrote various ways and means of automatically
controlling the power output of transmitters. Thanks very much.

Presumably control is needed to limit the power dissipated in the
output transistors which involves a time delay. And, which is a
different thing, to place limits on the instantaneous
collector/emitter voltage.

In my Icom 735 transceiver the first control requirement appears to be
met by by placing a limit on the DC collector current or power input.
The second requirement appears to be met by feeding back a
gain-control voltage proportional to the magnitude of the reflection
coefficient of the load impedance. I may not be entirely correct.

Reg.

Allan -

Contact Charles Penniger, KC9DAO of Penniger Radio in St. Charles, IL
(western suburb of Chicago). He has a web site: http://www.penninger.com

He deals with aluminum tubing on a regular basis with his full-time job --
and stocks long lengths. An e-mail or telephone conversation will likely
save you time.
http://www.penninger.com/prod05.htm

The McMaster-Carr warehouse for the Midwest & Chicago area is along TriState Tollway (I-294) between Grand Avenue and North Avenue ... they have a pick-up window for locals !! ... and are less than 1 mile from my QTH.

That and Charles Penniger, KC9DAO -- who sells aluminum tubing up to 24 feet in length (Chicago area) -- start with Chuck -- and save yourself grief and large shipping or freight charges.

Another method of PA protection is thermal protection of the PA,
sometimes integrated with cooling fan control. In my experience, where
drive control is deployed, it reduces drive to prevent the heatsink
exceeding about 60 deg C. I have found such protection commonly on
commercial FM land mobile equipment (two way radios), some amateur FM
mobiles, and less frequently in HF equipment.

>
>In my Icom 735 transceiver the first control requirement appears to be
>met by by placing a limit on the DC collector current or power input.

You are right, some radios do incorporate over-current protection of
the PA. It is in some Icom radios (IC706IIG, IC7400 / IC746PRO), and I
suspect many other Icoms will share this feature.

Whilst probably intended for PA protection, it has the great benefit
that the radio is less likely to draw excessive current while
adjusting an ATU, and tripping over-current protection in a power
supply. A radio that needs 16A in operation, but 25 during tune is a
pain in the butt on a nominal 20A power supply with over current
protection that kicks in above 22A!

>The second requirement appears to be met by feeding back a
>gain-control voltage proportional to the magnitude of the reflection
>coefficient of the load impedance. I may not be entirely correct.

As I described, and for example, from the IC706IIG service manual:
"The reflected wave signal appears and increases on the
antenna connector when the antenna is mismatched. The
HF/50 MHz reflected signal level is detected at D10 (FILTER
board), and is amplified at the APC amplifier (IC1091c) and
applied to the ALC circuit as the reference voltage."

You are probably (almost certainly) correct about the 735 having a
"reflected power" limiting circuit, but Icom's view seems to be that

if you want to read their description of how the radio works (if you had an interest in that sort of thing), you need to purchase the service manual.

Where is all this leading Reg?

Correction, Rohn purchased this tower design from "Spalding" -- and not
Sterling as listed in my original post !

Also, this same tower is used for the HyGain AV-18HT or "HyTower" 53 foot
vertical antenna -- which MFJ now sells for $849 !!

Thanks for the reply, David.
I've pretty much decided to rent a tiny "track hoe" and dig
down to the hardpan, to make sure it's not just some rocks
I can remove... assuming the hardpan is, in fact, there, I'm
going to just go with whatever depth I can get, and add about
20% to the total amount of concrete the mfr stated....and also
do "overkill" on the rebar. I have both the original "T" base
the tower was mounted on, as well as a brand-new one the
fellow-ham I got it from gave me...concrete here in FL is rapidly
approaching the cost of solid gold, "IF" you can get it,
so, no room for mistakes...
He also gave me the bolts that went with the new base, abt 3'
long.... I *think* the bolts are UST items, everything else is.

Thanks for your reply; this isn't the only place I've asked the
question... and it's like pulling teeth to get a response worthy
of consideration...

Best 73,

Well, off-topic or not, I recently plooked a hot little blond number,
about 25, fair complected, in the back of a CHAPMAN UNITED
VAN LINES vehicle, and, I can only concur with the original poster.
We made an *awful* mess of an ottoman, some sort of large mirror,
and, although it was very, very dark back there, it's always a good
idea to wash dishes and eating utensils that have been transported
from Point A to Point B by such companies.
So, I cannot reccomend using CHAPMAN UNTIED VAN LINES for
the transport of items.

Hi All

Just some more details. The signal is to be distributed to 4 of my neighbours and therefore the switch is out of the question unforunatly.

The more i read about seperating almost each channels as Ian & Crazy George describes the more I like the idea. This will give me the posibility to adjust the level of each. And since I do want to do some DIY then building BP filters which not interact should be a task to overcome.
The cray part of this project is that the only reason for that I want 21,39 and 47 on antenna two (TRIAX unix 100 vertikal pointing at 200 degrees) is because i am a TVDx'er and those three ones are extreme DTV fringe ones from 200 km away. Actually only the ch 38 on Ant. 2 is the only one to be used by my wife and neighbours.
The antennas are place 100 meter away on the heighest point omf my property.
So actually all this is because I want to be able to "snif" whether the conditions are good or not everywhere in the house and that is also the reason that i am interested in to get as much of the UHF band covered with ant 1 which is the WIZI EZ 74 (One of the biggest UHF ever produced). Its pointed toward 70 degrees (I live 8 km south south east of Roskilde in Denmark) and in that direction I got the baltic contries.
The ant 1 is to be used for the following regular programmes 22/25 DTV schweden 23 local copenhagen 33, 43, 50 Analog Schweden
The rest of the channels in the downlead from this is ant 3 31/53 Danish analogue TV (DR1 TV2), 51 soon to come Danish DTV.
ant 4 ch 45 analogue Danish TV vertical (DR2)
So its just one of those really crazy DIY projects to see if it is it at all possible.:-))

At the moment it all works with the 21, 39, 47 left out from ant 2 through a one channel amplifier. (I have put up an experimental unix 100 on 6 meters of waterpipe on the roof terrasse (very low WAF wife acceptance factor) to try out the 21,39,47) until I get this up and running.

Best regards

Svend Holby

Frequency is selected by the receiver, not the transmitter.

The transmitter is OFF when I do it manually and I tune for maximum
noise in the receiver. How do YOU do it? <smiley>

If I can't do it when the transmitter is ON then neither can an
automatic ATU. It would have to be more clever than I am.

I freely admit, I've never touched the things... just trying to be
helpful :-)

But what do you think "maximum noise" means? You hope it's going to mean
maximum field strength when you come to transmit, but what does that
actually mean in terms of loop tuning conditions?

>If I can't do it when the transmitter is ON then neither can an
>automatic ATU. It would have to be more clever than I am.

If we're not clever enough to build an automatic ATU for a magloop, it's
a sign that there's something about magloops we still need to know...
not abandon the idea.

First of all, somebody needs to build a phase detector for an existing
manually tuned loop, and see what results it gives.

Ian, Reg, I don't for a moment think automation of a loop tuner is
trivial, but I don't think it is impractical with modern processor
control techniques. For a practical solution, it will probably need
some king of position sense from which to derive end limits and
velocity for implementing a second order control loop.

It is probably a lot like autotuning a PA tank (and that was done in
closed loop linear systems decades ago), except that the loop Q is
probably much higher and the tuning range wider. The same problems
will be encountered in finding the true resonance where phase changes
very quickly from a large positive value to a large negative value or
vice versa depending on the direction of tuning.

It would be interesting Reg, just the install an SWR meter (this is not a windup!) at your magloop, shut your eyes and tune it up on rx as you describe, then see whether is is close to minimum SWR)which will probably be at or very near zero reactance) on tx.

To some extent, the tuner algorithms will be simpler than for a two to n variable tuner (many autotuners vary more than two components, they may switch in an autotransformer, or change from L to PI or PI-L configuration).

I am more interested to hear from someone who says it can't be done, what they tried that didn't work.

A remote autotuner could be just the thing that makes a magloop a very attractive, small, frequency versatile antenna (well, for those who don't have the antenna in the shack or very long arms).

Owen

==========

We are able to analyse and predict the behaviour of magloops to any required degree of precision.

What is missing is how both a magnitude-searching and phase-searching circuit of an automatic tuner works when denied access to the magnitude-searching component.

When manually adjusting a tuner it is obvious to the operator that the controls INTERACT with each other. Both variable controls equally affect both magnitude and phase. That much can be gleaned from inspection of the circuitry.

For example, in the case of a T-tuner with two variable capacitors, the operator cannot concentrate on one variable exclusively to the other. He continually has to swap from one to the other and obtain a balance by progressively closer approximations whilst keeping his eyes on the co-called SWR meter.

An automatic tuner manages to complete the operation by varying both controls simultaneously. But it is obvious from observation of what the drive motors are doing, and the time taken to do it, that the circuit is behaving just like a human operator. Occasionally the motors even have to reverse and try again.

When denied access to either one of the two variable controls, the automatic tuner doesn't know what to do next and would become lost.

If the desired impedance magnitude is known to be 50 ohms and is somehow inserted in the circuit, this is of little assistance to how the circuit behaves because when the main loop is off-resonance the actual resistive component is miles away from 50 ohms yet the automatic tuner is obliged to do something about it. But without the ability to vary the diameter of the coupling loop, as I say, it is lost.

So we need something different from and more sophisticated than the conventional automatic tuner with its relatively simple magnitude and phase-searching abilities.

I'll believe it when I see one which works.

Regarding your question about manual tuning up for maximum noise (or signal) in the receiver, at the frequency set by the receiver, reciprocity rules and fortunately, with modern transceivers, one can bawl into the microphone and answer a CQ call with confidence that it can be heard.

But Ian, you already know all this. I have the time and I just like gabbing about it.

I trust you are comfortably settling down in your new country. I have spent happy years, in bits, working in Scotland. It is a most civilised place.

Yours, Reg, G4FGQ

Line loss on transmit is relatively unimportant. What matters is
accuracy of tuning up an extremely high Q loop on both transmit and
receive.

Owen,

I cannot but agree with everything you say and am inclined to say it can't be done automatically with anywhere near to the required degree of accuracy.

The obvious automatic way of tuning the loop is to use a remotely controlled signal generator at the other end of the back yard and tune up for maximum signal on receive. This should not be very difficult to arrange but it is too uneconomic to be practical.

So I'll stick to manual tuning.

But I hasten to add that I hope this conversation does not deter anybody from experimenting with magloops because magloops are, by far, the most power-efficient of all the small, space-saving, neighbor-friendly antennas.

Try one on the 160, 80 and 40 meter bands. At higher frequencies there's usually enough space to erect a dipole or an inverted-L which will perform at least as well. (Ian, you could perhaps do a useful article on the subject.)

For the basic design, download program MAGLOOP4 from the website below.

Cecil, while you are tuning your screwdriver, which is not a magloop,
phase and magnitude does not enter your head. Forget all about it!

Watching the SWR meter while tuning my screwdriver while driving
had always bothered me. I first installed an audio VCO so I
wouldn't have to watch the SWR meter. Next I installed a flip-flop
so I only had to get the screwdriver started in the right direction
and didn't have to hold down the toggle switch. When the SWR starts
dropping, an LM-339 shuts off power to the screwdriver motor. And
it's all done while my IC-706 is in reduced power tune mode.

As Reg said, reciprocity rules.

You can also satisfactotily tune an antenna to resonance by adjusting it for maximum output. When I was in Tierra del Fuego we had Land Rovers and boats equipped rith RCA single-sideband HF radios.

The Rovers had whip antennas atop fiberglass boxes containing loading coils and motor-driven tap-changing switches. The coil base-loaded the whip.

I routinely tuned the whips by switching my multimeter to the a-c range (it used germanium rectifiers) and tuning for a maximum meter indication. I chose meter-probe positions for a convenient scale indication.

The above was accomplished with the transmitter ON and fed with a test tone driving it to put out some power. The whip was mostly non-directional so it made little difference where the r-f sensing antenna was placed. The tuning procedure worked fine even with the multimeter in the near-zone laying on the bonnet (hood) of the Rover.

The capacitor tuning a high-Q loop could also be tuned for maximum output because that is your goal. The sampling antenna could be located almost anywhere but probably not in a null of the loop.

Best regards, Richard Harrison, KB5WZI

I don't know much about small loops. Modern transceivers,
like my IC-706, have such good protection circuitry that
it can be tuned into any load at full power. Is there
anything in the design of a small loop that would prevent
full power plus foldback tuning?

Terman says in his 1955 edition, page 99:
"The standing-wave ratio S is one means of expressing the magnitude of the reflection coefficient;---."

This, Terman illustrates can go either way via formulas. Rho is convertible to SWR and SWR is convertible to Rho.

Why should an indication proportional to SWR not be so calibrated and called ?

"Locomotive Breath"

In the shuffling madness
Of the locomotive breath,
Runs the all-time loser,
Headlong to his death.
He feels the piston scraping --
Steam breaking on his brow --
Old Charlie stole the handle and
The train won't stop going --
No way to slow down.
He sees his children jumping off
At the stations -- one by one.
His woman and his best friend --
In bed and having fun.
He's crawling down the corridor
On his hands and knees --
Old Charlie stole the handle and
The train won't stop going --
No way to slow down.
He hears the silence howling --
Catches angels as they fall.
And the all-time winner
Has got him by the balls.
He picks up Gideon's Bible --
Open at page one --
God stole the handle and
The train won't stop going --
No way to slow down.

Maybe off-resonance operation. The small loop is always inductive but its reactance is high and its resistance is low, so it has a high-Q. It has almost uniform current thoughout, so this produces nulls on its axis.

Hi Richard,

My model is only valid providing the coax has no current on the exterior of the shield. All I did was extend one leg of the dipole by the length specified, but not actually connected to it; with a 1.2" gap. As per the following sketch.

----------o---------- ----------
dipole extension

Do you think it makes sense? It is the only way I could think of modeling it with NEC.

Hi Wes,

I wouldn't say so. I took the time to enter your data into EZNEC and
confirm your results. I haven't closely examined the implications of
construction variations for the skirt wires, much less the "choking"
action that is notably missing.

Hi Frank,

No. The extension lies in the null of the dipole. As such, it would
be no mystery that it has so little influence.

To model it correctly requires some form of cage or skirt of wires as
Wes has provided in this thread.

yes, this is a common problem. try checking out the arrl's radio direction finding book for more specific techniques. but a couple simple ones are
1. a small loop, use the sharp nulls off the ends of the loop instead of the big wide lobes.
2. a doppler system that electronically rotates antennas to give direction. there is a very simple one on my web site at:
http://www.k1ttt.net/technote/doppler.html
3. a pair of phased verticals set up to give a cardioid pattern, again use the sharp null not the fat lobe.

Jim,

Assuming your transmitters are NOT super well filtered I would build a
yagi for 3 times the frequency (498-501MHz) and listen on that frequency
when very close. Very few transmitters will be so clean as to not be
able to hear the 3rd harmonic. I DF and do running ARDF very often and
if you don't mind the small second antenna and you have a receiver that
can tune to the 3rd harmonic this will get you both the needed
attenuation for being close and the ability to pinpoint the source.

You already got two good suggestions from others. Here's a third.
Build a MOXON square, less gain than yagi but if built right the MOXON
has a very distinct readward null, you exploit the null. Another
small advantage is it's smaller than a 2 element yagi for the same
band.

Allison

The doppler shift method mentioned by Dave has worked very well for me
but it only gives you a chioce between 2 directions. If you know the
kind of area your turtles are likely to be then it should work
otherwise you can use iyt in conjunction with you yagi antenna to get a
accurate direction. The doppler shift method (unlike directional
antennas) is not affected by signal strength. This is because it works
by using two small antennas and determining which one the radio wave
hits first (this type of device usually generates a tone which
dissapears when the wave hits both antennas at the same time). This
tells you with a good degree of accuracy that the transmitter is in
front of or behind you.

Hi Jim

Hams will quite often get involved in hidden transmitter hunts during field day games. You might be surprised at the expertise out there.

Some notes/thoughts for you;

- I'd be surprised that the yagi would exhibit 48dB F/B and if it did it would only be for a very narrow frequency range. This however isnt a huge problem. Even 20dB is more than ample for hidden TX finding.

- Ensure that you arent cross polarized with the turtle antenna. It is possible for polarisation to change as the signal reflects off objects so reflected signal maybe stronger than the direct. This only gets to be a huge issue at cross polarised (say) plus or minus 10 degrees or so so just make sure you are in the ballpark.

- Something that you modeled probably didnt allow for a ground so close and your body so near. What I am trying to get at is you may not be getting anything like the performance you expected because of these local detuning effects.

- I'd suspect that the problem might actually be more in the receiver than antenna. As the signal gets stronger/closer the radio might be running out of signal reporting range,. ie everything is just over a certain value so it is treated as being at maximum. It is quite common under these conditions to switch in an amount of attenuation to reduce the signal to a more reportable figure. This usaully goes in the antenna feedline.

- In addition to the above your receiver may not be very well shielded such that signal actually bypasses the antenna/coax path and thus gives you less peaks and nulls to go off. You can check this by placing a dummy load (usually 50 ohms) in the antenna cable socket and checking for the nearby signal.

- The human body is excellent for using as a directional attenuator. If you had a simple omni antenna attached and only a few inches in front of your body you'll get maximum attenuation (lowest signal) when you are facing away from the target turtle.

- If you antenna design isnt symetrical and there is an imbalance of currents in the coax you may get to receive a signal directly to the coax as well as the antenna. A few ferrite beads at the antenna feedpoint around the coax, coiling the coax in a 4" dia 5 turn loop or using some other form of balun (coaxial or otherwise might help. Obviously you can test this theory by playing with the coax orientation

as well as the antennas.

- Considering also using the null or side of the antenna. ie turn it at right angles to the turtle and where you get a very sharp loss of signal thats the direction (or 180 degrees out) the TX is.

- Trying to narrow the beamwidth probably isnt a useful exercise with the size limitations you have. You stated 90 degrees (3db down) beamwidth. With (say) a 12 element yagi, 20ft long the beamwidth is around 38 degrees. Better but probably not useful for you.

Hope this is useful to you.

Oh and a question. Is the box turtle the one one that has the hinged flap in front? I found one on a busy road and I picked it up and moved it along in what I hope was the direction it was going. Had never seen one before! (New to the US)

Cheers Bob W5/VK2YQA

actually... for some reason i didn't put it on that web page, but you can have a unidirectional null with that simple system. to do that you make the antennas 1/4 wavelength apart and make one feed line 1/4 wave longer than the other. in this way you get a cardioid pattern since the only direction that won't have a phase shift is when the signal gets to the antenna with the longer feedline first and the other one exactly 1/4 cycle later. just be sure to take the coax velocity factor into account.

It might not be so simple as that-- as, depending on lengths, and
element diameters, and how they are attached to each other, can get much
greif, even with 6061-T! Had a Six Meter yagi, useing this tubeing thru
the boom (3/16 inch -diameter), and could drop it from height and not
damage it- But, in the wind, the elements would chatter, causing metal
fatigue, causing element failure at the boom entry hole. Don't know if
there is a program that will calculate mechanical stress from items
such as mentioned, but it is something to reckon with. Its kind of
distressing when you have 4 (or 8!) of these up, on a moonbounce
array, and have to find a way to replace those elements! as info-

I wrote an article on the Inverted L with a remote autotuner (designed for end-fed wires) some time ago. The configuration, it is frequency agile, very convenient when integrated with transeiver auto-tune controls, and works a treat. The most significant downside (like most Marconi, Windom, Long Wire etc configs) is from an EMR safety point of view, it has a radiator within reach of people standing on the ground. The article is at http://www.vk1od.net/InvertedL/InvertedL.htm .

With the experience of using such a configuration, I reckon that a magloop with an remote autotuner designed specifically for a magloop would be a great option for people with very little space, better than Echolink!

Reg, if you have an expression for the loop inductance and resistance as a function of frequency, and we could make the assumption that the coupling coil is a broadband ideal transformer with a fixed z ratio or otherwise characterise the transformation as a function of frequency, I could do a software simulation of an autotuner... be an interesting project.

BTW, the tuner values in the article above are found through simulation of an automated L tuner, but the 3 variable binary searching algorithm used for performance would not work for a loop.

I know it is common practice to tune screwdrivers for max power out from IC706s (tuning for "maximum smoke"), but is that good for the tuner?

Perhaps that is why Icom incorporated low power tuning of its system tuners. The AH4 actually presents a very limited range of Z to the radio, it effectively introduces a small attenuator at the tuner input when tuning. So the radio is limited to around 10W, the Z excursions are limited, and the tuner relays operate at quite low power. I wonder what they know that we don't?

Perhaps it is why Kenwood drops carrier before each relay operation in autotuning the TS2000 internal tuner. (Some of their earlier models have a reputation for tuner relay failure.)

It may be that tuning screwdrivers under full power isn't detrimental (I just don't know), but it is probably not safe to generalise.

Hi Cecil, Looking at the MFJ site and trying to reverse engineer the loop tuners they sell...They monitor the loop current to get resonance, tune for maximum. Then they have an "L" network to match 50 ohms. They have a Butterfly style Cap. for HV., and monitor the current as it is adjusted. Have a 50 ohm cross needle swr bridge to detect a 50 ohm match, for their matching control. I assume their "auto loop tuner" looks at the same stuff.

Let's not forget that the antenna on the turtle will not polarized in
any particular fashion so antennas such as dopplers may not show nulls
and may show peaks incorrectly. I would take a yagi that I can rotate
to match the polarization to the source any day over TDOA or doppler
type antennas. Also I would always favor hunting the peak versus the

null especially if any reflections are present. If you are having problems with a full sized yagi is it due to equipment limitations or to physical constaints such as vegetation?

Source record: 69096

I have tried entering the model shown in EZNEC 4

The "View" of the antenna looks fine but when I try to run the
simulation it reports that it cannot because the gain is negative.

I then changed from azimuth to elevation simulation but this time it
reported the maxim 500 segments were exceeded.

I then reduce the segments slightly but now the program reports Runtime
error M6201: Math Sqrt Domain error.

ie. Cannot get the model to work using EZNEC. I'll see if it will run in
MNANA.

Ahhh, you beat me to this.

Now, if the receiver IS well shielded enough, if you can insert a
switchable attenuator in the coax, you can reduce the signal strength
significantly...and, FM receivers get very non-linear below about 20dB
quieting, they quiet faster than the actual input. In otherwords, you
could get 3-4 dB quieting change for 1dB of singal change. What this will
do is make you antenna pattern SEEM narrower.

What I used to do was to change to an RF field strengtth meter with a
small cavity filter tuned to the frequency I was hunting when I got
really close.

>
> - The human body is excellent for using as a directional attenuator.

> you are facing away from the target turtle.

YES! But, you need to keep you body completely symetrical, stick an elbow
out and you will distort the pattern. Also, when the signal gets large

enough, remove the antenna.

In all transmission lines, including coax, there are various shapes of transverse electric and magnetic fields that can exist for the particular transmission line geometry. For each shape, the "propagation constant" can be calculated. Many transmission lines (at lower frequencies) have only one shape with propagates with low attenuation. The other shapes can exist, but their "propagation constant" is such that they decrease exponentially with distance. The propagation constant for each shape can be calculated, and is often a function of frequency.
When there is a discontinuity in a line, other shapes than the usual one must exist at the point of the discontinuity. (for example, in order to ensure that the transverse electric field is zero the surface of a conducting shape that is part of the line discontinuity). Thus, these other shapes exist (at a certain amplitude) at the point of discontinuity. The amplitude of the other shapes decreases exponentially at distances away from the discontinuity. The rate of the fall-off will depend on the particular shape, according to its propagation constant.
Thus, the distance needed to be back to regular old TEM propagation in a coax will depend on the particular discontinuity, and the propagation constants of the "higher order modes" or different field shapes, of a coax line.
I have seen examples worked out for waveguide propagation and a step change in waveguide width. There are probably worked examples of coax discontinuities in the literature, also.
These non-propagating shapes are usually called " evanescent modes", and this would be a good search term to use to investigate this further.

The SG-230 seems to handle 100 watts just fine. It is
interesting to listen to an autotuner tune up a transmitter
equipped with foldback. Clickidy-Click, the signal goes from
S5 to S9. If the foldback circuitry failed, then there would
probably be a bad outcome.

Assuming foldback and reflected power not invading the remote
tuner, I don't see why any harm would be done. 'Course, I'm
suffering from macular degeneration.

Jim wrote:
"What kind of antenna design could I switch to when I get to close range that would have a narrower beam so I could pinpoint my target?"

J. Roy Smith, W6YA described what he called "the simplest of DF loops, with no ambiguity of direction" in CQ magazine`s 1963 "Antenna Roundup". Roy also called ot the "Nobaloop".

Roy said it was designed for locating signals on the 10-meter band but has been used with reasonable success on the lower frequency bands. Roy used the loop on 80 transmitter hunts winning first place 15 times when many of his competitors were using identical loops.

The loop is about a 1-meter length of 1/4-in. dia.copper tubing (gas line) bent into a neat circle. The two ends are flattened for about half an inch in a plane perpendicular to the radius. Number 28 holes are drilled through the flattened tubing about 1/4-inch from the ends. The loop is attached to a coax receptacle such as Amphenol 83-IR or military type SO 239. One loop end is attached to the outer conductor by a 6-32 screw through one of the four holes. The other loop end is placed over the receptacle`s center conductor lug and soldered well.

The small loop gives a figure-8 response in the plane of the loop. The attached coax distorts this pattern, adding its vertical response, like a sense antenna. The resulting pattern is a cardiod.

Nearby vertical objects may need detuning to avoid interference with the vertical loop.

The maximum lobe is about 30-degrees wide.

The null is about 5-degrees wide, according to the author.

I have not built it but it seems simple, small, and easy to duplicate.

Best regards, Richard Harrison, KB5WZI

Let's face it - English is a crazy language. There is no egg in eggplant, nor ham in hamburger; neither apple nor pine in pineapple. English muffins weren't invented in England or French fries in France. Sweetmeats are candies while sweetbreads, which aren't sweet, are meat. We take English for granted. But if we explore its paradoxes, we find that quicksand can work slowly, boxing rings are square and a guinea pig is neither from Guinea nor is it a pig.

And why is it that writers write but fingers don't fing, grocers don't groce and hammers don't ham? If the plural of tooth is teeth, why isn't the plural of booth, beeth? One goose, 2 geese. So one moose, 2 meese? One index, 2 indices? Doesn't it seem crazy that you can make amends but not one amend? If you have a bunch of odds and ends and get rid of all but one of them, what do you call it?

If teachers taught, why didn't preachers praught? If a vegetarian eats vegetables, what does a humanitarian eat? Sometimes I think all the English speakers should be committed to an asylum for the verbally insane. In what language do people recite at a play and play at a recital? Ship by truck and send cargo by ship? Have noses that run and feet that smell?

How can a slim chance and a fat chance be the same, while a wise man and a wise guy are opposites? You have to marvel at the unique lunacy of a language in which your house can burn up as it burns down, in which you fill in a form by filling it out and in which, an alarm goes off by going on.

English was invented by people, not computers, and it reflects the creativity of the human race, which, of course, is not a race at all. That is why, when the stars are out, they are visible, but when the lights are out, they are invisible.

PS. - Why doesn't "Buick" rhyme with "quick"

Sorry I'm too tired to look up a better example, but
http://members.aol.com/BmgEngInc/Adcock.html
is still pretty good. It's essentially about like the
"phased verticals" the other fellow mentioned, in that
they both result in a "cardioid" pattern, i.e. a sharp
notch in the pattern, broadside to the array in this
case. That notch will be far sharper than any beamwidth
in gain that a Yagi can possibly have, and, a notch is
what you want, close-in, rather than overloading your
receiver. The one I used was built by another ham, and
IIRC the twin-lead between the two vertical elements was
some weird, 50 or 75 ohm twinlead, which is going to be
hard to find, and it was crossed, as hinted at in the lower
diagram in the URL above, but I think it probably just
connected to the coax to the rig at that point, rather than
any sort of "Combiner Box" like that shown. We used them
to DF a guy who was jamming a 2M repeater net every week.
We had cheap compasses, like you'd have on a boat,
fixed to the broomstick "boom" of the array, and it was
suprisingly accurate at to where all the lines intersected
over a period of time. Don't know what ever happened;
it was coming from inside a secure telco property, so we
couldn't do much "up close and personal" and FCC did
not show up as they were allegedly scheduled to do the
night I was involved.

Just surf around for "Adcock" and DF, antenna, whatever,
and I'm sure you'll find what you need. The Doppler antenna
the other fellow mentioned are spiffy, but I don't know how
inexpensively they can be done. Last time I saw one, it
was a dedicated, factory built unit... maybe these days
it's possible to "power" the logic with a laptop or something..
It'd be very simple to scale a 2m (144-148 MHz) antenna to
your band...

Good luck..

I did not notice that somebody had attempted what you suggest. I translated the coordinates into regular NEC2, and it does run. It appears to violate some NEC2 criteria, but not sure how critical the model is. Obviously I cannot use the "Minninec" ground, so have substituted an average S/M ground with the coax end about an inch above the ground. I had assumed the antenna was for HF, so it is probably impractically high, causing multiple lobing. A free space model might provide more meaningful results.

Does it matter that the outer sleeve and radiator element are connected
together in the model ?

The actual antenna only connects the sleeves to earth braid and the
centre conductor does not touch anything ?

Message-ID: <e2bd0$434aabe2$d80c3c80$26657@NAXS.COM>
Source record: 69171

This isn't strictly a Ham question, but I hope you all can help me anyway.

I am using small transmitters in the 166-167 mhz range in some Box Turtle research I am doing. My RDF antenna is a 3 element Yagi designed via Yagicad 4.1 which works pretty well. It has 48db front/back and about 90 degrees beamwidth in the H pattern.

This works well for initial locating......usually starting 1500 to 2000 feet from my transmitter, but the closer I get, the more inaccurate it becomes.

What kind of antenna design could I switch to when I get to close range that would have a narrower beam so I could pinpint my target? It would be nice to have something smaller than my 35" x 21" yagi for close in work, but the beam width is the primary concern.

Yagicad doesn't let me design solely on beam width (at least I haven't figured out how) so is there another way to go on this??

Thanks
Jim

Hi David,

ALL connections contribute to radiation. Their combination is what
builds the familiar lobe characteristic.

>The actual antenna only connects the sleeves to earth braid and the
>centre conductor does not touch anything ?

That's one way, the convention - could be t'other way 'round too; and
perhaps more interesting.

>
There are actually three variable controls in a C-L-C T-tuner. For
minimum internal losses (mostly in the L) the inductance needs to finish
up at the smallest value that will allow the two Cs to achieve a match.
To do it right, there should be some stepping of the L, until it won't

match any more, and then a step back to the last set of values that did match.

>If the desired impedance magnitude is known to be 50 ohms and is
>somehow inserted in the circuit, this is of little assistance to how

Not sure what you mean here (that thing about "inserted in circuit" wasn't anything I intended to suggest or imply).

Back to loops...

>But without the
>ability to vary the diameter of the coupling loop, as I say, it is
>lost.
>
Hang on - who varies the diameter of the coupling loop in routine operation? I thought we were only looking for something that would help a correctly functioning loop to track up and down the band.... in other words, to operate the tuning control for us.

Like Owen, I'd still be very interested to learn what "maximum noise" on receive actually means in terms of R and X and/or phase on transmit.

>I trust you are comfortably settling down in your new country. I have

All agreed. Along with the math that Cecil has retrieved and quoted
again, everything points towards the distance in question being a
function of coax diameter only; and not wavelength.

Sorry, Richard, apparently my attempt at irony fell flat. Let me put it another way:

The instrument can only make measurements at the point on the line where it physically IS. Therefore the Bird 43 cannot be measuring "SWR" by sampling the maximum and minimum voltages at locations further up and down the line.

Therefore it follows that the instrument must actually be measuring something else... namely, what you described in your follow-up:

>Why is there power from the reverse direction for a Bird Model 43 to
>indicate? There is no second generator sending power in the peverse
>direction. The reverse r-f comes from a reflection. The coax enforces a

Yup. It measures the reflection coefficient of whatever impedance is
connected to the port on the opposite side from the transmitter. This
measurement is made at one physical point along the line.

The subsequent conversion to VSWR is a mathematical relationship only.

>The Bird has been satisfactory for about a half century.
>
As I've often said before, you don't need to defend the Bird 43 to me.
I own and use one, and admire the design. It only needs to be defended
from weird notions about how it works.

==========
No, it doesn't.

It measures the MAGNITUDE of the reflection coefficient. It discards
the information which is contained in the phase angle of the
reflection coefficient. As a consequence the only use which can be
made of the magnitude is to calculate the SWR on an imaginary 50-ohm
line. The SWR can be used to calculate the magnitude of the
reflection coefficient.

Reg.

Sorry, I left that important word out.

> As a consequence the only use which can be
>made of the magnitude is to calculate the SWR on an imaginary 50-ohm
>line.

Agreed. SWR has become a number that indicates the general "goodness" of an impedance match. It is almost always determined indirectly, by actually measuring something else and then calculating an SWR value.

The only way to measure VSWR truly and directly is to find the points of maximum and minimum voltage along the line, and measure the ratio of those two voltages. That is the classical definition of VSWR, but hardly anyone measures it that way, because it requires physical access to all points along the line. But if they do, then...

>The SWR can be used to calculate the magnitude of the
>reflection coefficient.

Engineers swap freely between the different available ways of expressing the "goodness" of an impedance match, choosing whichever one is the most convenient (or conventional) for the application.

Believe me, the transmiters are not well filtered at all. In close range I easily get 2nd, 3rd, 5th, etc. harmonics.

I'd try the 3rd harmonic antenna, but my receiver doesn't go beyond 173 mhz or so, so I can't receive the 3rd harmonic.

I thought I'd be smart and have Yagicad design an antenna for the 2nd harmonic and then use it with my current receiver. I suppose you can guess the results from that failure...there is almost no null or beam width at all (360 degrees I guess). Oh, well.

Thanks
Jim

True, I haven't thought of everything, but I have done this:

The yagicad design, which others have used very successfully for foxhunting antennas, should work o.k. at 3 or 4 feet above the ground, right? My transmitter antennas are horizontal trailing insulated wire. I have a fairly long cable so am able to hold it at arm's length from my body. It does have a very good null and I use both front and null in my RDFing.

My radio might not be the best as far as sheilding.....it is plastic cased. So I made a fiderglass holster for it with aluminum screen embedded in the fiberglass resin all the way around...kind of like a Faraday cage. I don't really know how this helps. It is not grounded, and I haven't really tested it out all that much. At a fair range I can receive my transmitters by connecting a rubber ducky antenna, and kill them when it is removed. SOMETIMES using my body to block the rubber ducky gives me a good null....but not good enough to RDF with.

Yes, the Box Turtle (several species in North America) is the one with the hinge on it's plasteron (the bottom "shell") which allows it to pull entirely in its shell and close up. Box Turtle numbers are decreasing thoughout thier ranges and will probably be rare over the next 50 to 100 years or so in many areas.

Thanks
Jim

To be picky, in most implementations, its response is a function of
the forward or reflected power provided that Zo is real, and the
magnitude of the complex reflection coefficient can be calculated from
those measurements.

Owen

I have a homebrew analog attenuator that has male and female BNC connectors that I can connect when necessary. It is variable 0 to 10 dB, and this sometimes helps a lot, but not always, and not when I get within 40 feet or so. I know this is not a problem when foxhunting (or is it?), but when there is a lot of brush and brambles and holes and such, I sure would like to reduce my hands and knees search area.

I worked with a researcher once that was able to locate his Bog Turtles under water within 6" to a foot via "pointing" the antenna (150 mhz). When the antenna pointed into the mud, he could stick in his hand and pull out the turtle......now that's good RDFing, and I don't expect anything like that, although the next time I'm taking measurements of his antenna to duplicate it if I can.

I am not familiar with a "cavity filter". I'll do some Googling on that. Can you fill me in on it's use?

Thanks
JIm

Owen,

Forward and especially reflected power are even more imaginary than
the SWR on a non-existent 50-ohm line.

The only use for forward and reflected power is to calculate the
magnitude of the reflection coefficient. And the only use for the
reflection coefficient is to calculate the imaginary SWR. And the only
use . . . . .

I understand meter manufacturers provide graphs, which, if you don't
know how to use a pocket calculator, will do the calculations for you.
But you will still go round in circles.

Reg.

Hi Ian,

This seems to be a particularly notable difference - to which
absolutely NO ONE has ever deviated from in ANY determination of SWR!

That is to say, this "mathematical" distinction that some rely on to
differentiate their arguments has not got one scintilla of difference
over any other method.

The only way to claim you "directly" measure SWR is to find some way
to place two probes of a meter along the line such that one probe goes
into the trough and the other into the peak and the meter reads SWR
directly. Unfortunately for rhetoric's sake, this STILL renders the
determination in terms of a mathematical relationship. It cannot be
escaped.

Why this keeps on being revisited must be to allow the new lurkers to
observe my correction.

Reg, I dug up some calculations from sci.physics.electromag
from about a year ago that indicate one foot of 50 ohm coax
on each side of the Bird is enough to make the line real,
i.e. not imaginary, and that's a conservative estimate.

OK. So a linear amp would be built with tubes to allow full flow of signal
without restriction, while an audio amp might be built with valves, because
we would want to control (restrict) the audio volume. :)

This thread seems to have a life of its own. From ally to this!

Amazing!

If you can operate your antennas in free space then they would be
meaningful.

If you can't/won't buy Roy's fine EZNEC program, then may I suggest
4nec2 at zero cost or MultiNEC at nominal cost as alternatives to bare
NEC.

My old Heathkit HM-15 SWR meter samples the peak forward and
reflected currents. A pot is used to set the meter to full
scale using a voltage proportional to the peak forward current.

When the voltage proportional to the peak reflected current is
then switched into the meter circuit, it reads SWR from the
precalibrated scale which is linear with |rho|, i.e. at half-scale,
SWR=3 and |rho|=(3-1)/(3+1)=0.5

In the model I supplied, the first wire (cleverly labeled "Source
Wire") contains the source. By modeling convention, a source must be
"on" a wire, so the wire connecting the upper radiator to the
skirt/sleeve is equivalent to the transmitter (coax center conductor)
and is *not* a short circuit.

Please forgive my previous senior moment.
It was ~2% of a wavelength at 10 MHz for RG-213.
It appears that one foot of coax on each side of
a Bird wattmeter is enough to establish Z0 at
50 ohms which forces Vfor/Ifor=Vref/Iref=50,
the necessary Bird boundary conditions.

I must have a dozen equations for SWR, all mathematically consistent
with each other. A lot of the math is performed by simply calibrating
a meter face. For instance, given a linear meter reading for |rho|
with full-scale equal to 1.0, SWR values can be applied to the
meter face with 3.0 at half-scale. (Ever notice how many SWR meters
have 3.0 at half scale?)

Actually, it is called an argumentum ad verecundiam, an appeal
to authority - a technical authority in this case. I don't know
Kevin G. Rhodes at Dartmouth. He merely answered my question on
s.p.e. that didn't find an answer on this newsgroup. Exactly what
did you find technically wrong with the following evidence?

****Quote****
Newsgroups: sci.physics.electromag
From: "Kevin G. Rhoads" <Kevin.Rho...@Dartmouth.edu>
Date: Tue, 07 Oct 2003 12:49:14 -0400
Subject: Re: Transmission Line Question

For 10 MHz I would expect that all other modes
would be non-propagating (i.e., evanescent) even though RG-213
is a large coax (improved RG-8 apparently). The speed of propagation
is listed as 66%, so the nominal wavelength is 3/2 times the free
space wavelength for the TEM mode. 3/2 x 30m = 45m, which implies
the decay rate in space for non-TEM modes is going to be large
as the cable diameter is .405" (jacket) which implies the
spacing from inner to outer conductors will be less than .203".
For order of magnitude estimate, assuming the lowest non-TEM mode
can be approximated using a characteristic equation that really
is only applicable in Cartesian geometries:
(1/45m)**2 = (1/.203")**2 + kz**2
Clearly, kz must be imaginary to make this work. thus an
evanescant, non-propagating wave:
kz**2 = (1/45m)**2 - (1/.203")**2
To the accuracy used to date, the first term on the right
is negligible, so the decay rate, alpha, can be estimated:
alpha**2 = - (kz)**2 = (1/2.03")**2
Or, the lowest order undesired mode should reduce intensity
by a factor of 1/e (0.37) in about 2.03"; power will reduce
by that factor squared in the same distance (.135). In
about four inches, undesired mode power is down to about

0.018, in six inches, .00248, and after a foot, 6.14x10-6

You should double check my algebra, but I think the estimate
is reasonable. To put it into other terms, since the wavelength
in the coax dielectric is 45m and the conductor to conductor
spacing is about 2", any non-TEM mode will suffer attenuation
in E-field intensity with a space-rate constant rounghly
equal to the conductor to conductor spacing. INtensity
drops by 1/e = 1/2.71828 every 2 inches. Power availalbe
drops faster, being square of intensity.

So unless almost all the power diverts into an undesireable
mode (by a factor of more than a million to one), one foot
of cable should see pure TEM at the end.

Even my double-needle meters have 3:1 as a vertical line
at the center. All of my single-needle SWR meters have 3.0
at half scale since they are actually reading |rho|.

Check out this humoungous one. Click on the small meter
picture for a full-size picture.

FWIW, the centers of my dipoles are near the top of a 40' tower near
the top of a hill behind my house. The ends of the 160m dipole are
about 8' off the ground, but about 60' to 80' below the base of the
tower. It works, but I don't have anything to compare it to. It's
the only mounting option I have unless I want to get a couple of
push-up masts to elevate the ends of the dipoles more. (They would
still end up below the base of the tower.

>
> Which criteria?

This is from L. B. Cebik. "Basic Antenna Modeling: A Hands-On Tutorial", page 2-9 published by Nittany Scientific; "Among the most important conventions to adopt is to begin at one end of each antenna element and to proceed from that end to the other without changing directions in mid-stream". I have seen array pattern reversals when this is not followed. There will also be current discontinuities. To be honest, with such a high segmentation this will probably not effect the pattern of such a stucture, or for that matter the input impedance. Just for curiosity I will give it a try, and see if it makes much difference. Also, although it should not cause any problems, I would not have used a single segment for the source, just the end segment from the upper element.

>>Obviously I

I had assumed the antenna was to be used on HF, still comparing models with similar parameters will provide meaningful information.

>>A free space model might provide more meaningful results.
>
> If you can operate your antennas in free space then they would be
> meaningful.

True, but the pattern is much simplified. Even so, in free space, I do see evidence of minor patter ripple. I have also read (Cebik again) where the Mininec ground can produce eroneous results.

> If you can't/won't buy Roy's fine EZNEC program, then may I suggest

> NEC.

I use Nittany Scientific's (www.nittany-scientific.com) NEC-Win Pro, which seems to be a fairly good implementation of NEC2. The program does contain

simplified (spread sheet) data entry, but I prefer to enter in basic code,
which is apparently not available in EZNEC.

EZNEC data can be entered from an ASCII file. I regularly
generate ASCII files using MS Professional Basic for entry
into EZNEC. Here's a quote from the EZNEC help file:

"Wire coordinates can be imported from an ASCII file in a simple
format, either replacing or adding to the existing model. This
can be used to import coordinates from another program."

==========

Cec, I still have a 30-watt, 160m, portable transceiver which I made about 20 years back. It's in an aluminium attache case and still works. In my travelling days I used to toss a wire out of the hotel bedroom window.

Lift the lid and on the front panel is a 1.5"-square moving-coil meter. It is used as a TLI on transmit and as an S-meter on receive.

The meter scale is calibrated 0-500 microamps.

But my imagination doesn't fool ME.

On receive, when the meter indicates 50% of full-scale deflection I know that the meter is actually measuring 250 microamps.

And on transmit, when the meter indicates 90% of full scale deflection I know that the meter is actually measuring 450 microamps.

Let this little anecdote be a friendly warning to they who use meters with a 0 to infinity SWR scale, or scaled in terms of forward and reverse power.

Reg, G4FGQ.

Thank you, you're right. The key difference between direct and indirect measurements is not about the need for mathematics; it's about the need for additional input from theory.

What I should have said is:

When you calculate the VSWR from measurements of maximum and minimum voltage on the line, that simple division formula comes directly from the definition of VSWR. The measurement is direct and completely self-contained, needing no further input from transmission-line theory.

But you cannot calculate VSWR from a single-point measurement of reflection coefficient unless without some additional input from transmission-line theory which connects them together. This dependence on additional theory is what makes the measurement an indirect one.

>the necessary Bird boundary conditions.

The Bird doesn't require any upstream and downstream boundary conditions. You can insert the instrument between any source impedance and any load impedance, and what it reports is entirely about the load impedance, unaffected by the source impedance.

However, it was scaled and calibrated assuming a 50 ohm system reference impedance, so in order to read correctly, it requires you to agree that your system reference impedance is 50 ohms too.

The element is trying to sample the voltage and current at a single point along the instrument's internal line. Because that line is physically quite long, it is built as an accurate 50-ohm line so that the instrument will cause minimal disturbance when inserted somewhere along a 50-ohm cable.

But Cecil, nowhere in the analysis you quoted does it estimate how much power is diverted from the dominant mode at the discontinuity.

If the explanation of the discontinuity is that some power is converted from dominant propagation mode to another mode, and that those other modes are evanescent, it seems that this analysis of the impact of the discontinuity considers only estimating the decay rate of the evanescent modes without estimation of the relative magnitude of the power diverted to those modes in the first place.

If the scale were linearly calibrated for |rho| = 0 to 1,
would you still be objecting?

SWR = (1+|rho|)/(1-|rho|) for 0 <= |rho| <= 1

When SWR = infinity, it doesn't mean infinite current
through the meter. It just means that Vref = Vfor
where |Vref|/|Vfor| = |rho|. My Heathkit HM-15 allows
for full scale to equal Vfor. Then Vref is applied.
The scale is a linear indication for |rho|. The
corresponding SWR scale just follows the above equation.

When Bird requires a 50 ohm environment, they are requiring
50 ohm boundary conditions for the reading to be valid. If
you install the Bird in a 450 ohm environment on both sides
of the wattmeter, for instance, it will NOT read a valid forward
power and reflected power. In a matched-line 450 ohm environment
with absolutely zero reflected power, the Bird will indicate an
SWR of 9:1, a |rho| of 0.8 and a ratio of reflected power to
forward power of 0.64 even when the reflected power is zero.

Owen,
You have obviously have extensive knowledge and familiarity with some equipment on this subject. I haven't studied this aspect of the radios I have yet, but offer the following from my design experience.

There are several relatively independent considerations which have been mentioned in this thread and I hope this clears up any confusion about which is doing what.

My understanding of the true purpose of (what we call) ALC is to prevent distortion in the final amplifier and the resulting "splatter" it causes, while allowing the maximum power out. As you so correctly point out, this originated in the linear amplifiers of old. Distortion at this point causes increased intermodulation (mixing) of the desired signal components and the resulting products appear out of the normal bandwidth = "splatter". There is always SOME of this going on, but as long as it is below about -30 dBc this is considered acceptable.
Because there is no Grid current to sense in solid state amplifiers, some other method of detecting the onset of distorting is required. Not knowing what _IS_ done, I can only speculate that knowing the highest level of output power which causes only a small, allowable increase in distortion, an output level detector can be designed which begins to provide feed back which cuts drive when this point is reached; thus paralleling the function of the grid current detection method of old. Because this is an instantaneous feedback system with a relatively high gain, the feed back voltage will exhibit a considerable rise as the device is driven closer and closer to the undesirable point. This must be what we are looking at that is called ALC on the front of the radio. As long as the level of this signal is within the manufacturer's limits, the distortion is limited to the specification and you are assured of the highest power with in-spec distortion.

With solid state comes other considerations which are actually separate from the distortion issue although from a circuitry standpoint they may seem identical. Because these devices have been and are still somewhat sensitive to mis-treatment and can be destroyed instantaneously, various methods are available to help save the devices. However, had they been easily available in tube days, they would have been equally applicable.

Sensing and placing a limit on collector/drain current is one method. Some load conditions can cause excessive current resulting in device destruction, so sensing over-current electronically and reducing drive can prevent this.

With the advent of simple reverse power sensing circuitry, another fault detection scheme can be used to reduce drive and protect the final power

device. Sensing SWR and reducing drive can prevent high device current and destruction, as well.

Heat rise can also destroy the device, so sensing device temp and reducing drive controls this also.

Because a design has one or more of these, the identity of each could be confused by combining the feedback signal and calling it only "ALC" when in actuality, there are two or more protection schemes present along with the (distortion limiting) ALC.

Quite wise.

Nevertheless, large currents are drawn by some radios in low power.

For example, I owned a Alinco DX70-TH and their EDX-2 autotuner. When it autotuned, the tx power was reduced to about 10W out, but it still drew in excess of 20A tuning into some loads on some frequencies... which would trip the overcurrent protection in one of my power supplies, so it was unusable on that power supply.

People do rough tune radios on full power, and I, like yourself, question the wisdom of that practice.

I designed a device to make manual low power tuning with an IC706x more convenient (http://www.vk1od.net/IC706TuneMate/IC706TuneMate.htm). It has been interesting that almost all of the feedback that I have received on the article is from screwdriver antenna users who insist that it is absolutely unecessary, they tune their screwdriver for maximum RF Po indication on the IC706x meter using full power in RTTY mode. (Achieving high RF Po indication depends indirectly on low VSWR because of the PA load protection scheme.)

I've always had a rule of thumb that 100 times the diameter of
the coax was enough length to 99% establish the TEM mode so
Kevin's explaination made sense to me.

Apparently, you are not satisfied with Kevin's explaination. Kevin
Rhodes email address is available on Google. The reason not to
publish it here is to avoid spaming his email account.

True enough, but in the context of the question as to whether the Bird
43 reads sufficiently accurately, the transmission line on which one
is interested in the decay of the evanescent modes is the Bird
Thruline coupler section, not Rg-213 or any other cable that might be
attached to the Bird.

(I am assuming your 450 ohm line to be an unbalanced line, impractical
as that is, but the issues of balance to unbalanced transition are
just noise to the discussion.)

Is this about whether the Bird readings are correct for the conditions
on the Bird Thruline, or whether the meter readings are extensible to
the adjacent transmission line without further interpretation /
modelling?

The Bird readings should be correct for the conditions on the Bird
Thruline. You can safely extend those measurements literally to the
adjacent line where the adjacent line is the same as the Bird Thruline
and of negligible loss. In other cases, knowing the line parameters,
you may be able to use the measurements to some extent to calculating
some conditions on the other line.

Though the Bird readings in your example for Forward and Reflect Power
cannot be assumed valid for the adjacent line, the net power should be
correct.

I don't think anyone is suggesting that the Bird could be used in a
general sense to estimate the VSWR on your 450 ohm line.

No, they're not. They are requiring a 50-ohm system reference impedance.

What you call the "impedance environment" consists of physical things like the source impedance, line impedance and load impedance. You're confusing those with the system reference impedance, which something completely different.

System reference impedance is purely a matter of definition. The most common choice is 50 ohms... and by definition, that means 50 ohms exactly.

Having made that choice, then you obviously design and calibrate your instruments to give correct readings in an impedance environment that is as close to your chosen reference impedance as you can practically make it.

Your example shows the difference between impedance environment and reference impedance most clearly.

> If
>you install the Bird in a 450 ohm environment on both sides

>SWR of 9:1, a |rho| of 0.8 and a ratio of reflected power to
>forward power of 0.64 even when the reflected power is zero.

You have changed the impedance environment to 450 ohms, and that's fine... but all of the Bird's readings are perfectly correct if the system reference impedance remains defined at 50 ohms. The reason why say they are incorrect is that you also changed your definition of system reference impedance to 450 ohms, without acknowledging that you did it.

It's like doing a financial calculation without mentioning that you switched into another base currency... darn right the results are not valid.

Yes Steve, once you have the gain control mechanism, it becomes the obvious control point for various over-x closed loop control systems. But you are right that the highest priority function is for limitation of distortion due to exessive signal (for the current conditions), and it is that loop that has the most onerous dynamic performance requirements (eg fast attack) for it to perform the intended fuction well.

Unfortunately, there is a growing common belief that unless the ALC meter is high upscale, then the rig isn't being talked up enough (the dumbing down of ham radio). There seems a common ignorance that most ALC detectors have a threshold (usually the rated PEP for solid state PAs), and that the slightest deflection of the indicator means that some peak signal has reached that threshold, further deflection causes greater gain reduction in the IF stages, causing the ALC to act more and more as a compressor where overdrive of the PA is likely to occur on transients during ALC attack time. Exceeding the red line, even for occasional transients, is to exceed the capability of the ALC to contain PA distortion due to overload. My thought is that if you want audio compression, use a speech processor, not the ALC.

Mentioning speech processors. A correctly adjusted speech processor is proably better protection against overdrive than depending on ALC alone. The peaks are contained (clipped) and the distortion products filtered off, before getting near the PA which does not have effective post filtering for clipping distorion.

>What I should have said is:

Hi Ian,

Remarkable touch of admission - especially to my over-arching method
of criticism.

Another point needs to be attended; the discussion of the measurement
of SWR seems quite, and absurdly, drawn in kindergarten terms of
mathematics as if the determination were king and the numbers simply
fell out be virtue of cranking the equation.

Nothing could be further from the truth.

As much as Reg pines away about what a SWR does not measure,
absolutely the same could be said for his unspoken inference that
probe measurement along a line does measure it.

True, probing the line reveals a pattern that in the mind conforms to
the expectation of standing waves, but this is simply trying to
measure your own shadow when each time you stretch out the rule your
shadow moves further out. What size is your shadow - when?

Using the formula everyone here leans upon as the archetypal equation
for SWR, and claiming they've measured at the appropriate points along
the line (undoubtedly only in their imagination) easily leads to
errors above 20%. Worse yet is that this same formula fails utterly
at the bench (am I embarrassing anyone?) for any but the most
pedestrian of SWRs which are easily resolved by a SWR meter in the
first place.

Beyond this issue of accuracy (certainly no one is interested in that
are they?) stands the fictions of requiring slightly more than a
quarterwave length, or access along the line to both the trough and
the peak. Anyone so hamstrung to NEED these criteria, hasn't ever
really faced the problem of measuring SWR on an open line in the first
place. The double-minima method offers an exceptional accuracy for
high SWRs and occupies a smaller region of line than otherwise
demanded. Measuring at the minima also reduces the error introduced
in the very act of measuring SWR.

To this last, how many here can guarantee their probes will approach the line with the same offset? There's a very good reason why SWR probes are mounted on vernier carriages. How many would recognize when the probes were too deep, or not deep enough to justify the measurement? To imagine any approaching the line with hand held leads raises the prospect of shooting marbles without thumbs.

As to these meters that everyone is rushing to use - Square Law or Linear? Don't know the difference? You don't know accuracy or how to obtain it when you have no choice. How do you render a Square Law detector linear? How do you linearize a Square Law detector measurement? No concern? You aren't measuring SWR then either. The method of measurement for low, medium, and high SWRs is not the same. One size does not fit all as the discussion in this group might imply (from that same lack of actually having done it). Even the math is different - and if any argue that this observation flies in the face of simple transmission line equations, then these casual tourists are comfortably remote from actually measuring the rough terrain of SWR.

However, none of this practicality is going to disturb the armchair SWR analyzer. It comes to their great fortune that one simple instrument will probably offer far more accuracy than they could ever obtain by trying to be literal about SWR "on the line."

Message-ID: <HIX2f.15350$U51.14571@news-server.bigpond.net.au>
Source record: 69071

Thank you to whoever provided the coordinates for the model of this antenna.

I wrote them down and entered them when I saw them in your posting but the original email has been automatically removed from the folder in my email client.

There has been a lot of discussion and side issues raised from my original post but I am grateful for you taking the time to provide the information for me.

I am a novice with regard to antenna theory and have no previous experience with antenna modeling. Your post has given me a good starting point.
I entered the coordinates and (beside initially selecting wavelengths instead of inches) the model ran fine.
I was then able to scale it up to the frequency of interest (920 MHz) and now I am playing with the sleeve diameter, sleeve length and radiator length to observe how these are effecting radiation pattern and SWR.

There was also mention of a book regarding basic antenna modeling, my next step will be to purchase a good book to help me understand the process and limitations etc.

Thanks again

Regards

David Huisman

Since Bruce hasnt responded

A cavity filter is a very narrow band filter usually of silvered copper pipe construction. At 160MHz its going to be about 18" long and maybe 3" dia. You might be able to get away with a helical filter instead. Thats a copper/silverplated coil inside a silvered/copper box. I'd suggest three coupled together if you were serious. They could then be in a (say) 4" x 2" x 2" box.

In this case the use is as a tuned TRF receiver connected direct to a RF measuring device. When you are close you simply watch the meter and walk towards where it gets stronger and away from where it is weaker!

I'll comment on your other post in a moment.

Cheers Bob

Source record: 69072

Hi again Jim

I'd suspect you need an attenuator of maybe 60dB in 6dB steps! I cant see the 10dB variable one as being useful. Of course at 50dB or more coax leakage might be an issue!

The other researcher you mentioned most likely dropped to signal strength only mode when they got close. Antenna directivity up close in my view isnt a viable way of doing it. As a rough guide you get a 6dB change in signal power everytime you double or halve the distance. This means that if you maximum signal measured distance is maybe 6ft and it must work out to 2000 yards then you have to allow for 60dB of measurement range. This is further complicated by the turtle antenna being at ground level, in fact in the mud and dirt. I dont know what that loss represents but I'd add 30dB to be sure. Your whole system then must have some method of measuring over that range of 90 odd dB and have useful directional nulls etc doing so. This is where the big step attenuator and antenna changing/removal help.

Should the antenna work okay? I guess the question is did you include the ground in the modelling? Obviously you'd get some major sky direction lobes/response from ground reflection but the worry is how it affects overall directivity. My gut feel is that the F/B would be markedly different and nowhere near the 48dB. At 1M above ground there may be sufficient detuning of elements to widen the frontal lobe but I doubt it would be a huge excursion. Do you find the null is much sharper than the frontal lobe? The bottom line though is that in your application it isnt as critical as someone (like amateurs) trying for maximum performance. This means I should stop complaining!

Okay on the screening. Well as I mentioned the test is to plug a 50 ohm load in the antenna socket and see if it responds at a distance of say 5ft. If it doesnt then dont worry about screening. If it does it depends on how much and then whether things like coax leakage have to be factored in.

I'll stop ranting/waffling on now..!

Cheers Bob

With the exception of the sleeve wires, the model follows this
convention and a trial with different end-to-end connections for the
sleeve gives identical results.

If someone doubts that the sleeve is effective or the model of same is
invalid, as I said before, remove it and place a parallel resonant
trap at the top of the "coax" running from ground to the bottom of the
antenna. The results will be very (but not exactly) similar.

With a one amp source, there will be a current standing wave on the
"coax" with a peak amplitude of approximately 1/2 amp. Changing the
height above ground changes this dramatically and the angle of maximum
radiation above ground changes dramatically as well.

Those wanting to spend more time with it can try adding wires to each
end of the sleeve, tying the wires together; changing the length of
the sleeve and re-resonating the rod, and so forth.

Because the top of the sleeve is a multiwire junction I prefer to use
a separate wire to hold the source.

Since I'm a long time client of Roy's and a beta tester for MultiNEC,
I use EZNEC with MultiNEC as a shell. I get the best of both worlds
and MultiNEC will also invoke Arie's fine program, which I use for the
neat full-color 3-D plotting. EZNEC keeps me honest with all of the
segment length checking, antenna viewing and other fine features.

MultiNEC offers full spreadsheet entry, and other features too
numerous to mention. It writes EZNEC input files just dandy. It will
do the same with your Nec-Win.

I didn't read it that way, Owen. IMO, the real question is:
What length of 50 ohm coax needs to be attached to the Bird
input and output to ensure that a 50 ohm environment is
present?

>I thought that was the subject of the discussion.

From an earlier post:

In the case of the Bird 43, I suggest that if had, say, at 1MHz, 75 ohm line and a 75 ohm load on the load side, that the V/I raio for the travelling waves in the region of the sampling element would be so close to 50 ohms as to not materially affect the accuracy of measurements on the 50 ohms coupler section, irrespective of the fact that the sampling element has only 0.02% of a wavelength of 50 ohm line on its load side.

(For avoidance of doubt, nothing in the foregoing is to imply the Bird 43 would be directly measuring or indicating the conditions on the 75 ohm line.)

I have changed the system reference impedance to 450 ohms. Assuming
a tube PA with a pi-net output, 50 ohms doesn't exist anywhere anymore.
The system reference impedance is no longer 50 ohms so the Bird wattmeter
is being abused and misused. You can do the same thing by using a DC
voltmeter on an RF voltage or by using a hammer on a screw. If you
want to know the SWR on 450 ohm line, use a 450 ohm SWR meter.

If there is 75 ohm coax on the input of the Bird, the reflected
power reported by the Bird on the coax will be off by an infinite
percent. That's pretty inaccurate.

The Bird does not measure or report the conditions on the coax, it
measures and reports the conditions in the immediate region of the
sampling element which is some 40mm inside the Thruline coupler
section.

I don't know what this argument is all about. Consider the
following:

XMTR---75 ohm coax---Bird---75 ohm load

Are you saying the Bird's placement will result in a reflection
coefficient of 0.2? I seriously doubt that is true.

I don't have the equipment at hand to do that experiment, but I have done another experiment.

XMTR -- 2m of RG58 -- Bird43 -- 1.2m of RG213 Bird43 -- 20m RG6 (75 ohms) -- antenna.

1.2m of 50 ohm coax between the Birds is 4.2% of an electrical (wavelength.)

I have made measurements with only one 100W slug which is moved from instrument to instrument.

The tx was adjusted to 100W forward on the first instrument.

Both instruments read 100W forward.

Both instruments read 2W reflected.

When I swap the instruments around, I get the same results. It is only a simple test, but I am not convinced that measurements from one position are signficantly different to the other position, despite the transmission line "environment" being different.

I am not surprised that both instruments read similarly, despite the fact that one doesn't have any 50 ohm coax on the load side of itself, whereas the other one does.

I don't have any argument with your results. Try this instead.

XMTR -- 2m of RG58 -- Bird43 -- 1.2m of RG6 Bird 43 -- 20m RG6 -- antenna

The second Bird will NOT indicate the actual SWR on the RG6.

I won't waste the time, I can predict that they will most likely be
different. Transmission line theory tells me that the Z in the region
of each Bird will be different, and that will probably result in a
different indicated VSWR.

It is a sidetrack, just noise.

The measurements I reported were identical, although one Bird was
surrounded by 50 ohm line, and the other had 75 ohm line on one side
of it. The 75 ohm line did not cause a measureable difference in meter
readings in that simple trial.

The main point of the discussion has been: An SWR meter
calibrated for Z0=50 ohms will not accurately report the
actual SWR on a line that is not Z0=50 ohms.

Of the four following configurations, in a lossless situation,
which one accurately reports the SWR on both sides of the SWR
meter?

1. XMTR---50 ohm coax---SWR meter---50 ohm coax---load

2. XMTR---50 ohm coax---SWR meter---75 ohm coax---load

3. XMTR---75 ohm coax---SWR meter---50 ohm coax---load

4. XMTR---75 ohm coax---SWR meter---75 ohm coax---load

Checking your lines of code more carefully, I see that they are all in the same direction, except for the small radials connecting the top of the sleeves. What I noticed is that the card sequence is not in order, which was why I was confused. Not sure how important this is.

What I have noticed is that similar structures (GP with depressed radials, for example) produce erroneous TRP results. It will be interesting to try such computations on variants of your sleeve antenna. My results did not show significant current on the outer shield of the coax. This may be due to my inability to implement the "Mininec" ground.

Nec-Win Pro does have a Pseudo built-in NEC-Win Plus interface, which allows spread sheet entry, and it will also interface with Excel. I am not familiar with MultiNEC, or EZNEC, although I do have ARRL's EZNEC version,

but have never used it. I understand that EZNEC is an excellent program,
thought it does not support NEC code entry, or the S/M ground.

I have both. In my opinion, the ARRL's modeling course book would a
better choice for those starting out in modeling. That isn't meant
that is limited. Anyone who finishes the course should have an
excellent understand of modeling and able to knowledgeably make
complex models using programs such as EZNEC or NecWinPlus+.

Nittany's book would be a better choice for those who prefer using NEC
card input formats.

Why wouldn't the meter correctly indicate the reflection resulting from
the mismatch between the 50 ohm wattmeter and the 75 ohm transmission line?

Owen,
Though this is not antenna talk...

Thanks for the confirmation of my half experience, half
judgment-based-on-knowledge based understanding.

> Unfortunately, there is a growing common belief that unless the ALC
> meter is high upscale, then the rig isn't being talked up enough (the
> dumbing down of ham radio). snip... My thought is that if you want
> audio compression, use a speech processor, not the ALC.

Interesting misconception. I'll remember this when I find that some
clarification is needed on ALC.
A good explanation "tool" is to say that the ALC "meter" deflection is an
indication of how much over drive you are trying to give due to too much
audio. I understand that it is an indication of the gain reduction being
applied to keep the PEP at the design max. If it is done correctly, it
should provide no compression effect at all.

> Mentioning speech processors. A correctly adjusted speech processor is
> proably better protection against overdrive than depending on ALC
> alone. The peaks are contained (clipped) and the distortion products
> filtered off, before getting near the PA which does not have effective
> post filtering for clipping distorion.
> Owen
> --

I'd be careful in saying it this way because it appears to connect the
compression concept with the over drive concept and they are independent
concepts. The purpose of ALC is to set the proper PEP level (highest, but
not "too much") and the purpose of compression is to improve "talk power /
intelligibility" by increasing the average envelope power (AEP ?) while NOT
changing the peak (improve peak-to-average-ratio of speech).

The question implies that the mismatch would cause appreciable
reflections. I have not witnessed that happening at HF but
perhaps others have. On MFJ meters, for instance, the one inch
wire through the ferrite toroid probably wouldn't cause an
appreciable mismatch.

I am in the process of designing a remotely tuned capacitor for a loop antenna. I have just received from Digi-Key a Modern Technology MTSD-V1 Unipolar Stepper Motor Driver Board. Unfortunately, the packing box did not contain a data sheet describing how to use the board. Digi-Key's catalog lists the board's capabilities but does not give information on how to connect to the board. A Google on the board did not give me any links to a data sheet for the board.

Has anyone ever used this board, and would you be able to copy the data sheet and send it to me? You can contact me at john@xgotwalsx.com (remove the two 'x' letters from the domain name).

The Bird manual shows a section of 50 ohm transmission line. But even the N connectors are 50 ohms. I assume even one of those would show up on a TDR.

Owen Duffy wrote:
> No Cecil, the thread subject and the quote of your text in the first
> message of the post was the main point of discussion:

Yes, the thread subject was the main point. Z0's other than 50
ohms do not force the V/I ratio to 50 ohms (for matched lines)
and 2% of a 10 MHz WL of RG-213 is of a *sufficient* length to
force the V/I ratio to 50 ohms.

>>The transmission line length must only be long enough such that
>>the V/I ratio is forced to the Z0 value. According to some pretty
>>smart guys I asked, that's about 2% of a wavelength.

I've already apologized for my memory being faulty on that one.
If what you want are additional apologies, you've got it. I
hereby triple dog apologize for my faulty memory. The above
statement was incomplete and was therefore wrong. What more
do you want me to say about it? It was wrong, so of course,
it "is not born out in practice".

> It seems that the statement you have quoted is not born out in
> practice, though I note that you "seriously doubt that is true".

What I seriously doubted being true is that a 50 ohm Bird wattmeter
has a 0.2 reflection coefficient when placed in a 75 ohm feedline.
I just don't think that 40mm (1.5") is enough length to establish a
50 ohm environment inside the Bird. But I might be wrong on that one.
I know my Autek WM-1 doesn't cause appreciable reflections when
placed in a 75 ohm feedline.

I think, from the beginning, you have confused what Reg said with
what I said. I am basically on your side in the argument.

Additional Context
The question of a year ago was not what is the minimum length
required to force V/I to Z0 (although that can be had from Kevin's
posting quoted from s.p.e.) I was arguing with Reg over whether
the lengths of coax into and out of *my* SWR meter forces V/I to
be 50 ohms. I use two foot lengths of RG-400. (That's ~2% of a
wavelength at 10 MHz.) Two feet is a *sufficient* length to cause
V/I to equal Z0 (in a matched line). Two feet is not the *absolute
minimum* length but is instead a *sufficient* length and the length
I use in my shack.

Source record: 68969

Some good suggestions.

One caution with "nulling" antennas. You say "small transmitters", so I don't know how much of a factor the following is. Also, if you are using the typical wildlife chirping transmitters, my #2 may not be completely appropriate:
When close to the transmitter, RF can enter the receiver directly, via the coax or just the receiver itself. When in the antenna null, this "Blow-by" can exceed the level coming via the antenna and make the null antenna useless. Loops are pretty simple, and the cardiod loop is pretty much an optimum loop.
There are two relatively simple solutions. Any of the phase sensing methods can solve this problem. (the Doppler is another solution, but it's not simple).
You can also take two or more "nulling" readings at a comfortable distance (terrain permitting) to triangulate the position. I even have a loop for 2M and one for 440 (cute little 1" diameter).

One is an offset attenuator. Google on that & you'll see a simple but very effective device except it won't narrow up your beam pattern.
A better, though a little more complex is what is commonly called the "TDOA". This is a two antenna phase sensing system which, when well made, gives an indication which allows you to walk right up to the transmitting antennas until the target is actually be in between the two antennas. These can find the keyed 5W. hand held in a shoulder-to-shoulder line-up of people all holding one. The one I designed has an extra FET (not a bunch of ICs) and a center reading meter which gives a left-right indication, nice but not necessary. I don't remember if I have an electronic package on it though.

No "u's" in my address.

Good luck, & 73, Steve, K9DCI

Hi all, I'm curious.

If you have an FM transmitter setup to transmit 150W and you put a thermometer about 15ft away with the FM antenna directly pointed at it, will the thermometer reading change?

If so, is there some sort of introduction that deals with temperature change based on antenna radiation?

Thanks!

Two things here.

The "offset attenuator" gets you the equivalent to a shielded receiver
without the shielding and very simple construction.

There are designs on the web for "quieting meters" and I have even seen one
design where the receiver s-meter signal was summed with the quieting signal
resulting in one very large dynamic range signal strength indicator.

Probably would, but would it cause appreciable reflections?
I don't think it would have |rho|=(75-50)/(75+50)=0.2
when used with 75 ohm coax. Owen said something about 40mm.
I just don't think 40mm (1.5") is long enough to establish
a 50 ohm environment but I could be wrong. I've never owned
a Bird. I suspect |rho| would calculate out to be much less
than 0.2. And of course there would be two discontinuities,
one from 75 ohms to 50 ohms and one from 50 ohms back to 75
ohms. Given the short length between those two discontinuities,
one probably interferes with and tends to cancel the effects
of the other as would happen with a zero length of feedline.

When you see the numbers for the Offset attenuator you won't believe them,
though true.

Thanks, Sluggo, but this is partly an oops!

The BMG pages are a very good resource (as are many RDF sites).

OOPS! The Adcock is just like a loop -- two nulls off both broadside faces.
The version that looks similar (previously mentioned) where you have two
vertical dipoles spaced 1/4 wave and a 3/4 wave connecting cross-feed line
gives the cardioid -- one null.

I don't see how the wires are numbered can be important; it's how they
connect, isn't it?

My rational for always (almost always) using wire 1 to hold the source
is that them I can add or subtract wires without having to change the
source wire designation.
>

Run it without any ground. Run it without any sleeve. Just put a
trap (or a high value resistor) at one end of a center-fed halfwave
vertical to represent the sleeve (choke) and then add various lengths
of wire on the other side of the trap. With no ground, the current on
the added wire will peak at multiples of 1/4 wavelength. So much for
the trap "isolating" the rest of the antenna.

I don't know what "S/M" ground is, but EZNEC supports perfect ground,
Sommerfeld-Norton and MiniNEC grounds. And I believe the object is to
not have to input files as NEC code.:-)

Let's say you had a one inch piece of 50 ohm coax in the
middle of a longer piece of 75 ohm coax. I'll bet the
reflections from one discontinuity would virtually
cancel the reflections from the other discontinuity.
After all, the math should work if the length of the
50 ohm piece is zero, or 1/2WL, or 1WL, or ...

In fact, a one inch piece of 50 ohm coax should cause
the same steady-state interference conditions as a (one
inch plus one wavelength) piece of 50 ohm coax. Don't
you agree?

So basically you want me to agree that it's ok to use 75 ohm connectors in a 50 ohm system - as long as you use two of them separated by 0, 1/2, or 1 (etc) wavelength. Could be true, I suppose. Still, I'd rather you tried it out on your radio first. :-)

2235. Mythbusters: V/I ratio is forced to Z0

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-12 22:09:51 UTC
From: Owen Duffy <owen@no.where>
Message-ID: <440rk1pg559akgta2q4d38s4le3noihnp8@4ax.com>
Source record: 68882

The myth: Measurements with a Bird 43 of the conditions on the Thruline section are invalid unless it has some minimum length of 50 ohm line on both sides of itself.

I have performed a test using components at hand where the Bird 43 has 75 ohm line on both sides of itself, and the test configuration is designed to present a 50+j0 ohm load at the point where the Bird 43 sampling element is located. The question is, how does the Bird respond?

The test in detail. Each component is in a list from the source to the load:

IC706IIG
1m RG58 with UHF connectors
MFJ949E ATU
3m RG6 (Zo=75 ohm) with BNC connectors
Bird 43
5.27m Belden 9275 (Zo=75 ohm, vf=0.83) with BNC connectors
50 ohm dummy load

Short adapters were used to connect to the Bird's Type N connectors, the dummy load's Type N connectors and the MFJ949 UHF connector.

The half wave resonance of the 5.27m length of RG6 was determined by s/c one end and connecting the other end via an adapter to a MFJ259B and finding the impedance dip at 23.05MHz. The calculated vf from this test is 0.81, which reconciles reasonably with the specs. Free space wavelenght at the test frequency is 13m.

The transmitter was set to 23.05MHz, and the ATU tuned to develop rated power output. The ATU is only used to present the rated load to the transmitter so as to obtain 100W for the test, to suit the Bird 43 element. It is inconsequential to the DUT (the Bird 43).

With this configuration, it is expected that the impedance at the Bird 43 is approximately 50+j0, and that there would be almost zero reflected power.

The Bird 43 indicated 100W forward power and a quarter of a needle width detection on reflected power.

The Bird 43 would appear to provide valid readings for the conditions on the Bird 43 Thruline section in this case, notwithstanding that there is not any 50 ohm transmission line attached to the Bird 43 + N-BNC adapters.

The myth that measurements with a Bird 43 of the conditions on the Thruline section are invalid unless it has some minimum length of 50 ohm line on both sides of itself is BUSTED.

Has anyone experimental evidence to the contrary?

Owen

PS: I hasten to add / apologise, I do not watch much television, but I was forced to endure Mythbusters when visiting a friend recently. It's about as scientific as what goes on here, so I thought the style appropriate!

Hello All,
I looked through the past threads about an antenna article that
has appeared twice in QST. The last article appeared in 1995 and was
authored by Robert Wilson, AL7KK. I'm thinking of building this type
of antenna, but wanted to change the element diameter from 1" to 1/2".
I tried to use EZNEC, but I'm having trouble setting the parameters for
the antenna correctly. Could one of the folks out there with more
knowledge of the program than I help me see what the change in diameter
will do to the antenna characteristics?

2243. Any experience using a Wonderpole?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-13 00:13:19 UTC
From: greg knapp 5 <gknapp@freshrain.org>
Message-ID: <h56dneQ3QPo8O9DeRVn-vQ@speakeasy.net>
Source record: 68890

I was seriously thinking of plunking down the $250 plus for the 40-foot Wonderpole (www.wonderpole.com) to support parallel dipoles (probably 14 gauge stranded copper wire dipoles cut for 80, 40, and 20 meters), fed with 600 ohm open wire, but I am concerned about:

1.. Is the pole strong enough to hold up 80, 40, and 20 meter dipoles, especially the top section?
2.. Do they, like most pushup fiberglass antenna, collapse or come loose over time?
3.. How do they stand up over time.I'd like to use it in a permanent installation.
4.. Do they need to be guyed (how badly do they flop around in 15-30 mph wind)?
5.. How much overlap do you leave between the sections for extra strength?
6.. Are they a good company to deal with?
I am thinking about mounting it on top of my 45 foot light-weight steel crank-up tower (no beam on it) to get my dipoles up 80 feet or so.

I called the company in Oregon (I believe), and they didn't know how it would work in such an application and the guy who is the mechanical expert never returned my call.

If anyone has any ACTUAL experience using a 40-foot wonderpole you could share with me, it would be much appreciated.

BTW, the reason for the multiple wires is to broaden the narrow pattern a single 80 meter dipole would exhibit on on the higher frequency bands (20-10 meters). But if it won't support it, I'll probably go with a single 80 meter dipole for now.

Thanks, and 73,

Greg, N6GK

A serious reply ... YES!

From Physics, temperature rise occurs when an object absorbs energy.
Now the construction of your thermometer will determine how much of a
temperature rise.

Glass bulb Mercury is one problem; glass bulb alcohol is a different
problem; coiled spring of dissimilar metals is another problem; etc.

The temperature will rise in all of them. The question is: "How much?" I
doubt it would be observed in ordinary household thermometers.

Now, put it in a microwave oven ....

Actually, the results of your experiment proves the myth to be true
and not to be a myth at all. There's 104.17 watts of forward power
through the Bird and 4.17 watts of reflected power back through the
Bird. Why does the Bird ignore those actual power values?

> Has anyone experimental evidence to the contrary?

Yes, your experiment. Assuming 100 watts delivered to the load, the
forward power on the 75 ohm coax is actually about 104.17 watts so
the Bird's forward power reading is in error by 4.17 watts.

The reflected power on the 75 ohm coax is about 4.17 watts so the
Bird's reflected power reading is in error by close to an infinite
percentage. The Bird 43 is reading neither of the actual power values
correctly. All you have just proven is that the Bird 43 gives invalid
readings when it is in a 75 ohm environment.

THERE ARE ABOUT 4.17 WATTS OF REFLECTED ENERGY FLOWING BACK THROUGH THE
BIRD AND THE BIRD COMPLETELY IGNORES IT. So the Bird is not even yielding
valid readings for forward and reflected power through itself. That's
exactly what I have been saying all along. If it were calibrated for
75 ohms, it would indicate the correct values.

I've built both. The Tape measure yagi is not nearly as good off the
back and a bit larger. Moxon well done is an easy 35+ db null off
the back and sharper.

Source record: 68896

My thought is that if you want
audio compression, use a speech processor, not the ALC....

For sure...Another problem these days is some radios
deal with ALC indication in reverse from each other.
IE: I *think* most kenwoods will show more indication
the closer to the edge you get, and if you were to disable
the ALC. the meter would show very high peaks, or maybe
even peg. But many Icoms are reverse. The closer to the "edge"
you set them, the lower the indication. Or at least on my older
730. If you see no indication, Houston, we have a nasty problem.
When you reduce power on an icom, the ALC indication increases,
and I think pegs, if you dial down to QRP range.
One thing that strikes me as real silly, are the ones that try to get
more power by disabling the ALC function. All you gotta do is
turn a trimmer...But it makes the radio nasty as all get out, and
is silly. Not to mention the extra power amounts to little in the
real world, and then you add on the extra wear and tear on the
poor radio...Silly... I hear stories of people getting 140-150-160
watts outa lil IC -706's and I just roll my eyeballs... Boy, I bet
it sounds great...Not...MK

not all.

Some of the antennas that fractenna, inc. supposedly manufactures were put up for a "test case" to some hams. I had initially requested to be one of those hams. after a small number of e-mail exchanges, I never heard anything further from fractenna, inc or any person there-in.

thus, I tend not to take that company, or its current CEO/CTO and resident "engineer" very seriously.

in fact, I tale exception to a company that has attempted to sue another company from overseas in an attempt to limit their ability to market a competing product here in the states.

so, my question is this: whats the real deal with fractal antennas and why is it that all information that can be found about them so vague in nature?

We're in complete agreement about those too.
We have 2 "groups" of metals that differ in having "um" or "ium" endings. It is only Alumin(i)um that "switches groups" in crossing the Atlantic. When, how and why did it happen?

The other one that is a consistent transatlantic difference is the group of words that include colo(u)r, odo(u)r, favo(u)r, hono(u)r..... I can't think of any "equivalent" anomalies there. ISTR hearing a radio show on language that mentioned that there is at least one variety of North American English that has kept the "u" - but I just can't remember who/where that is.

Doesn't sound like a good idea. There will be enough coupling between the
antennas that there is a chance you will burn out the front end of the TV.
If the TV has protection diodes on its inputs, that will be a source of TVI
when you transmit.

Dave wrote:
> math please??? where do you get 4.17watts?? to me it looks like a 50 ohm
> load on a 50 ohm meter so zero reflected power.

Here's the setup.

100W--tuner--75 ohm coax--Bird--1/2WL 75 ohm coax--50 ohm load

Assumptions: Losses are negligible. The tuner provides a Z0-match
so 100 watts is delivered to the load, i.e. all reflected power
is re-reflected. I think this was actually the case for the experiment.
Also assume that the impedance bump caused by the insertion of the
Bird is negligible, i.e. the same net voltage and net current exists
whether the Bird is in or out of the circuit.

The voltage reflection coefficient at the load is (50-75)/(50+75)
equals -0.2. That makes the power reflection coefficient (-0.2)^2
equals 0.04, i.e. 4% of the power incident upon the load is reflected.
If 100 watts is delivered to the load while 4% is being reflected
then the power incident upon the load is 100w/(1-0.04)=100w/0.96=
104.1667 watts. Incident power minus delivered power = reflected
power so the reflected power on the 75 ohm coax is 4.1667 watts.

The SWR on the 75 ohm coax is (1+|rho|)/(1-|rho|)= 1.2/0.8 = 1.5
THE SWR ON THE 75 OHM COAX IS 1.5:1. The Bird is in error when
it reports the SWR to be 1:1. The SWR is *NOT* 1:1 anywhere on
the load side of the system.

The Bird reports a forward power of 100w. The actual forward power
is 104.1667w. The Bird reports a reflected power of near zero. The
actual reflected power is 4.1667w. The Bird reports an SWR of 1:1.
The actual SWR is 1.5:1. The Bird is reporting false values because
it is embedded in a 75 ohm environment and is calibrated for 50 ohms.

If the ratio of voltage to current equals 50 within a 75 ohm system,
there exists an SWR of 1.5:1 and an SWR meter calibrated for 75 ohms
will verify that fact.

Dave wrote:
> math please??? where do you get 4.17watts?? to me it looks like a 50 ohm
> load on a 50 ohm meter so zero reflected power.

Let's compare the following two configurations.

100W--tuner--75 ohm coax--Bird--1/2WL 75 ohm coax--50 ohm load

100W--tuner--75 ohm coax--Bird--1/4WL 75 ohm coax--50 ohm load

The actual SWR on the coax is the same in both cases. The actual
forward power and reflected power are the same in both cases.
The SWR on the coax is 75/50 = 1.5:1. The actual forward power
is 104.1667w and the actual reflected power is 4.1667w.

In the first case the Bird will report an SWR of 1:1, a forward
power of 100w, and a reflected power of zero simply because the
ratio of net voltage to net current is 50 ohms at the Bird
measurement point.

In the second case the Bird will report an SWR of 2.25:1, a
forward power of 117.4w and a reflected power of 17.4w simply
because the ratio of net voltage to net current is 112.5 ohms
at the Bird measurement point.

The ratio of net voltage to net current alone is useless for
calculating SWR unless the Z0 environment (characteristic impedance)
exists and is known. Minus the humor, I believe this is Reg's main point.

STOP!

you can not assume this, especially if you consider the actual results of
the experiment. the bird is a 50 ohm transmission line segment and it is
seeing a 50 ohm load. the 50 ohm load plus 1/2 wave of anything is 50 ohms.
so as far as the bird knows there is no reflected power and the real world
reading is correct.

Did I miss something? As far as the Bird is concerned, all it sees is 50
ohms, indistinguishable from a 50 ohm termination, on its connector.

Remove the Bird, reconnect the two pieces of 75 ohm coax, and I'll
bet you will measure 70.7 volts and 1.414 amps at that point, 1/2
WL back from the 50 ohm load. If so, the Bird is NOT changing the
conditions when it is inserted. And we know there has to be reflected
power all up and down the 75 ohm coax. There is no place in the system
on the load side of the tuner where reflected power is zero. The
reflected power exists and the Bird reports a bogus reading for it.

With or without the Bird in the circuit the ratio of net voltage
to net current at the measurement point, 1/2WL away from the 50
ohm load, will be 50 ohms according to transmission line theory.
That's all the Bird is seeing - a V/I ratio of 50 which is irrelevant
to SWR unless Z0 is known and Z0 is known to be 75 ohms, NOT 50 ohms.

The ratio of net voltage to net current is All THE BIRD EVER SEES.
"As far as the bird knows ..." it is embedded in a 50 ohm environment.
But the Bird is not all-knowing. In this case, it is embedded in a
75 ohm environment and is giving bogus readings because all it sees
(samples) is a net voltage to net current whose ratio is 50 ohms.

It is what the Bird doesn't know that is important. The Bird doesn't
know that it is not embedded in a 50 ohm environment, and in its
ignorance of that fact, reports bogus results.

The actual SWR on a lossless line doesn't change. Yet, in another
posting, I showed that moving the Bird 1/4WL closer to the load
caused a reported SWR change by the Bird from 1:1 to 2.25:1. How
could both results possibly be right?

Exactly the point, Frank. The Bird doesn't know it is embedded
in a 75 ohm environment and reports bogus results because it
assumes it is embedded in a 50 ohm environment, which it is not.
This is Reg's main point in wanting to call the SWR meter a TLI
meter.

The Bird is not to blame for reporting bogus results. It is the
operator who is to blame for using a 50 ohm meter in a 75 ohm
environment and reporting the bogus results as valid.

100w--tuner--75 ohm coax--x--1/2WL 75 ohm coax--50 ohm load

Without a Bird installed at point 'x', most everyone would
agree that the SWR all up and down the 75 ohm coax is 1.5:1
and the voltage and current at point 'x' are the same as the
in-phase voltage and current at the 50 ohm load.

The voltage at point 'x' is 70.7 volts, and the current at point
'x' is 1.414 amps. The SWR on the line is 1.5:1.

Now, installing the Bird at point 'x' doesn't change anything
appreciably. The voltage at point 'x' is still very close to
70.7 volts and the current at point 'x' is still very clost
to 1.414 amps. Those two parameters are what the Bird samples
and all the Bird sampoles. And since the Bird is calibrated for
50 ohms, it reports a bogus SWR of 1:1. If the Bird is recalibrated
for 75 ohms, it will report the correct SWR of 1.5:1.

obviously at 1/4 wave from the load the impedance seen by the bird is not 50 ohms. you just can't ignore that internally the bird is a 50 ohm line, even though it is only a couple inches long it is 50 ohms, put a 50 ohm load on it and it will read no reflected power. this is just how it works, you can't wish it to be anything else, especially when the actual measurements prove me correct. you may try to assume away the bird and its characteristic impedance, but it just won't go away as evidenced by the real world measurements. you have to realize that the bird is not measuring what is going on outside it's case, the only thing it can measure is the voltage and current in its little 50 ohm internal world. so look at it from the meter's point of view... it looks out the load side and sees 50 ohms, it can't know that it is really a 75 ohm line, in fact it can't know there is any line there at all, it just sees a 50 ohm load, therefore no reflection into the meter, and no reflected power reading. qed.

That's the whole point, Dave. The poor ignorant Bird doesn't know what
is going on external to itself. You and I have to be smarter than the
Bird and not report its bogus results as "correct". The Bird reports
a 9:1 SWR on a matched-line 450 ohm ladder-line. Is the SWR really 9:1?

> this is just how it works, you
> can't wish it to be anything else, especially when the actual measurements
> prove me correct.

The actual measurements prove you wrong! The forward power reported by
the Bird is NOT the actual forward power. The reflected power reported
by the Bird is NOT the actual reflected power. The SWR reported by the
Bird does not exist anywhere in the system on the load side of the tuner.
The Bird is totally confused because it is being abused by the operator.
The operator is totally ignorant when he reports the readings are "correct".

> you have to realize that the bird is not measuring what
> is going on outside it's case, the only thing it can measure is the voltage
> and current in its little 50 ohm internal world.

That's exactly the point and that's why some readings reported by the
Bird are obviously bogus when compared to the broader knowledge of
actual external conditions. The operator needs to be smarter than the
Bird.

> so look at it from the
> meter's point of view... it looks out the load side and sees 50 ohms, it

But you and I know that 75 ohm reflected energy is flowing through the
Bird and the Bird is ignoring it. Of course, we cannot blame the Bird
for the bogus readings. We can only blame the ignorant operator who reports
that the bogus readings are "correct" when they are obviously false.

On Thu, 13 Oct 2005 00:02:33 -0700, N7ZZT - Eric Oyen
<n7zzt@127.0.0.1> wrote:

>so, my question is this: whats the real deal with fractal antennas and why
>is it that all information that can be found about them so vague in nature?

Hi Eric,

In a nutshell, the fractalists have hi-graded the field to offer us
what they say are the characteristics of the "class" of fractals.

Hi-grading is a mining term to mean that only the best ore deposits
are sought and mined, leaving the rest for waste. A miner might sell
you Gold Mountain, but to be sure, that mine follows only the vein,
already tapped out, and the rest of that dung hill is exactly that.

Hence, the fractalists have looked at everything that has a fractal
form, and discarded the losers. They keep the best performers, polish
them up for papers and trade shows and present them as the exemplars
of this new mathematics of RF.

Problem is, that when you ask about that mathematics, and how it fails
to explain the losers of that same class they discarded, the
scientific enquiry turns to legal suit pivoting on the point of your
attempt to poison the commercial market place.

In other words, there is never an explanation of why some are so good,
according to this new math, nor that other examples of that math are
so bad (according to that same math). To put it bluntly, they have no
method to forecast just what it is in the math that points to
performance. The math, as it always did, points to the shape -
interesting doodles. Unfortunately, this is not something that you
can stand up in front of the VC crowd and offer as a way to achieve
ROI.

On the other hand, in my work has shown a correlation to the math. It
is a very simple correlation. The more kinks you put in the wire, the
more resonances appear.

Simply put, examine a standard dipole over a range of frequencies, say
from 0.1F to 5F of the dipole's resonant F. There are n resonances
for a dipole. Taking that same length of wire and changing its shape
to a fractal (or any other for that matter) will produce m resonances.
You will find that m > n. Also, at the high end of the F scale
(towards 3F,4F and 5F or more), and for a characteristic of 300 Ohms,
the antenna becomes quite broadbanded.

This points out one of those "marketing" opportunities so often visited upon us here in years past. The claim that fractals offer multiband operation AND are broadbanded is true, separately, but the claim is often crafted to sound as this is simultaneously achievable. Whenever we examined this crafted claim, the arguments were always turned away or the claim "explained" by parts, but never as a whole. In other words, only the best examples of a fractal ever exhibited such dual characteristics, and often barely then and frequently from a practical Ham perspective (as to which bands) never very different than say an OCF Dipole (which can make the same claims by the way).

So, once you got your foot in the door, understood the basis of design, and the return on your investment (roi in less than caps); then you could stand back and try to imagine a third iteration Sierpinski dragon in your back yard for 2M through 160M. Then the blood would drain away, and you would black out.

All such fractal qualities have been investigated by me and reported at:
http://www.qsl.net/kb7qhc/antenna/fractal/index.htm
This offer of a link rarely fails to put the reader to sleep, so indulge only late at night if you prize the day. To my experience, absolutely no writer that has offered any interest in fractals has ever pursued it more than half a dozen postings. Once you strip away all the claims and simply look at the data, and the most general characteristics; then there is something to discuss - none seem interested even though it goes to the heart of antenna design.

You need to keep thinking about that. What if they are both right? Is it really one continuous, uniform transmission line? Is SWR the same everywhere in a tee stub circuit?

well DUH! obviously if you want to measure swr on a 450 ohm ladder line you
don't use a 50 ohm bird! anyone using a 50 ohm bird has to expect results
to be referenced to its internal 50 ohm line. i.e. if you actually do
measure no reflected power so you know the load on the bird is 50 ohms, and
if you really are in a 75 ohm environment then you can compute what the swr
is on the 75 ohm line... just don't expect the bird to show it to you
directly.

Dear Cec,

I assume you are referring to me, Reg Edwards, G4FGQ.

Before responding I have found it necessary to have several glasses of Australian, Banrock Station, 2004, Shiraz Mataro, Red. It can be recommended with confidence.

I have only ever had ONE point. It is that arguments and discussions about SWR, invariably involving "ifs" and "buts" and vivid imaginations of the contributors, are of entertainment value only. In any event, CB-ers and novices are unlikely to learn anything from it.

There is only one transmission line on which SWR matters. It is that which runs between the so-called SWR meter or tuner and the antenna. It is generally unknown. But whatever it is the so-called SWR meter, even a Bird, is incapable of measuring it.

Having got that off my chest. now perhaps I can finish the bottle with a cigarette.

Reg, G4FGQ.

This is the poor carpenter blaming his tools. The instrument can only be valid within its presumed operating conditions. Deliberate misuse is not a reason to crow about inaccuracy.
>The SWR is *NOT* 1:1 anywhere on the load side of the tuner.
This is the poor carpenter asking for his wage for his "craft." The Bird is accurately responding to the operating conditions it is found within. The manufacturer of the Bird wattmeter makes no claim as to the state of match BEFORE the meter; and especially when it is so obviously and deliberately misused - which in this sliver of specificity is transparent to the reading.

What is being busted is the claim that a necessary condition of operation for the Bird was the requirement for a length of 50 Ohm line to "force" a purely mythical presumption. That myth has been exposed and discarded.

- -

Owen,

To respond to your last question:
>>Has anyone experimental evidence to the contrary?
is consistently NO. Your own time at the bench has already drained the pool of ability in that regard. Your only expectation ever after having bellied up to the bench is to watch your work being gummed to death.

However, for completeness' sake, and as no one here really understands what accuracy is about anyway, there is one factor to be considered. The numbers offered verge on the limit of the Bird's ability to resolve a power anyway. There is a built in probability of ï¿½5W of error from the get-go, and any snake oil salesman can craft an argument leveraging that error to prove anything. We have seen that ï¿½5W error in the form of an argument that uses both + and - (not simply one or the other) to please a theory.

Owen, the same experiment with a deliberate mismatch of 3:1 would be just as effective at busting the myth AND providing data that overwhelmed the inherent meter inaccuracy.

There was no error in the reading beyond the inherent ï¿½5% specified as
the meter movement's. Owen no where at any time makes any appeal to
measuring or presenting SWR so the following claim is entirely
fabricated to present something not under his, my, or other poster's
consideration:

>and report a bogus SWR as "correct" who are at fault.

Persistence in wedging a new picture into a valuable frame does not
make it a classic portrait by a master of the craft. This finger
painting being offered is no more notable than yet another tacky Elvis
on velvet.

No, it wouldn't. The answer is exactly the same. *NOWHERE* is
the SWR 1:1 or 2.25:1. In both examples, the SWR on the coax
is 1.5:1. The SWR is *always* set by the relationship of Z0
to the load. In both examples above, that relationship is
identical.

> Amazin', what happens when you change the circuit!

Z0 didn't change. The load didn't change. Therefore, the
SWR didn't change. What exactly do you think changed?

The Bird is supposed to measure power. The Bird's forward
power readings are in error unless used in a 50 ohm
environment.

I previously talked about using a hammer on a screw. I was
hoping even you could understand that metaphor without me
having to explain it to you.

I think the circuit changed. Don't you? I also think that if you change the circuit, it's possible to measure the effect of that change. The meter measures what takes place at its insertion point in the circuit. What you seem to be upset about is that it might not in every case accurately display the conditions at some arbitrary position away from its insertion point. Like within a shorted quarterwave stub for example. Are you still unwilling to accept that the meter itself can present a perturbation?

obviously the problem here is that cecil thinks he is the only one that
knows better than to try to measure reflected power with a 50 ohm meter in a
75 ohm coax.

Richard, if you don't understand why a 50 ohm power meter yields
erroneous readings when installed in a 75 ohm environment, I
don't know what else to tell you. What is it about using a
hammer on a screw that you don't understand?

You at first essentially implied that a Bird wattmeter calibrated for
50 ohms yields valid readings in a 75 ohm environment. I was questioning
whether you were in your right mind or not. Others have been strangely
silent on the subject. Still others seem not to have gotten it yet.

The circuit changed without changing the forward power,
reflected power, and SWR so nothing of interest to the
present topic (V/I ratio) changed.

Do you know what dictates the SWR in a distributed network?
Certainly not the length of the feedline or the removal
of a tuner (assuming lossless conditions).

i'm not agreeing with how you assume the 50 ohm impedance of the meter out of the circuit. and i am not agreeing that there should be reflected power measured by the meter in the case of the 50 ohm load on the end of a 1/2 wave 75 ohm line. obviously it will not measure any reflected power which is perfectly correct for the whole circuit as defined and as actually measured.

Any error of misunderstanding Owen's post is entirely your own.
My career in calibrating RF Wattmeters while you were flipping bits is
a good indicator of the tectonic trench you stand in.

The fact remains, there has been no error displayed (beyond the casual
5% reading error inherent in the meter) nor his results refuted as to
how much power has impinged upon the cabled load as he explicitly
described being attached to the Bird's measurement port. As there is
no other use for such a wattmeter, any appeals to the contrary are
idle chatter.

Owen's claim stands: the myth of requiring a 50 Ohm transmission line
at the measurement port of the Bird wattmeter has been debunked. This
comes as no surprise but for one poster to this board.

Entirely OT:

Reg, you are way to impatient. There are very few Australian Shiraz
that should be taken in less than three years.

I can't recall the "instructions" on the back of the bottle that tell
one what to drink it with and when to drink it, but Banrock Station
produce "everday drinking" quality reds that should stand a few years
cellaring, but most wines in this part of the market will state "enjoy
now" for marketing purposes.

IIRC, the labels carry a bit of a story on their wildlife refuge, do
they get to tell you what to eat with it?

Anyway, now that it is open, enjoy it.

Owen

I fully expected someone to object, not only to object, but to do so
without any original experimental evidence and to devalue the
experiment that I did so that some readers who do not have even a
meager understanding of transmission line theory fall to being
convinced by whoever is most tenacious is defending their position.

>just as effective at busting the myth AND providing data that
>overwhelmed the inherent meter inaccuracy.

Indeed, and I considered a number of other experiments that did so,
but this one was based on components at hand, and should have been
easily understood by a person with the most basic understanding of
transmission line theory. It was important to surround the Bird with
line different to 50 ohms.

I expect the argument to twist an turn, to focus on everything but the
assertions that:
- there should be approximately a 50+j0 Z presented to the load side
terminals of the Bird Thruline (ie the ratio of V/I is 50+j0 where V
is the net or forward and reflected voltages, and I is the net of
forward and reflected currents);
- the Bird Thruline is a 120mm section of 50 ohm transmission line;

- in the region of the Bird Thruline sampler element, the ratio of V/I is approximately 50+j0;
and that the observed Bird 43 readings were reasonably consistent with those assertions.

The arguments that knowing that the Bird measurements are valid at the point of measurement is of little value are unrelated to the issue and a diversionary tactic, but wrong nevertheless. I won't add to the diversion to identify them.

I will extract the essence of the analysis and write a separate web page on it that may in the longer term assist others in their development, go being "gummed to death" doesn't totally devalue the information behind the case, and it might just be the cost of exposing the proposition to review.

Thank you for your support.

Owen

PS: I am planning my next mythbusters (oh no! I hear...) Myth: SWR meters measure SWR. Now this is not to bag SWR meters, I think that they are very useful instruments, but they have limitations, and the greatest problem is not the meters, but probably the knowledge base of those (ab)using them.

Kinky antennas?! Gotta love it.

check out this patent on non-fractal kinky antennas:
US6603440: Arrayed-segment loop antenna
http://www.delphion.com/details?pn=US06603440__

I have many EZNEC4 models of just such antennas, and have constructed may of
them
(which makes sense, since I'm the author). By the way, it was challanging to
get this patent
through primarily because of the nearly all encompasing Fractal antenna
patents. But I did it.

I don't think you understand what I was saying. It takes a
certain length of feedline to establish a Z0 environment
for the forward and reverse traveling TEM waves, i.e. to
force Vfor/Ifor = Vref/Iref = Z0.

> and i am not agreeing that there should be reflected power
> measured by the meter in the case of the 50 ohm load on the end of a 1/2
> wave 75 ohm line.

I never said it "should" measure that reflected power. What I
said is if it doesn't measure the reflected power that exists,
it is not giving a valid measurement of reflected power. A properly
calibrated meter will indeed measure the reflected power that exists.

The Bird does not know squat about transmission lines, foreward, or reflected. It only cares about impedance. If you connect a 50 Ohm load to it through 1/4 wave of 75 Ohm coax, the impedance the Bird sees will be transformed to 112.5 Ohms; hence the 2.25 SWR. (Actually, a 2.25:1 impedance ratio)

I have a computer simulation of that type of meter, which lets me do things you can not do in the real world, for instance having a 50 KW source on each side of the meter. It can separate out the signals in the two directions of transmission, but only when it is terminated in 50 Ohms, when there are no reflections.

Jim, if the ratio of net voltage to net current is already 50 ohms,
then your Bird "impedance discontinuity" should cause that to change
but there is no evidence whatsoever that it changes anything. Conclusion:
The insertion of the Bird does not appreciably change the V/I ratio.

Owen, there was absolutely no reason for anyone else to do any
additional experiments. Your own experiment proved that the Bird
wattmeter was ignoring the 4.1667 watts of reflected energy flowing
through it when installed in the 75 ohm environment. You proved
exactly the opposite of what you were trying to prove.

Is it only valid for AM and FM measurements?

I know its receiver sensitivity.

Is it Signal divided by Noise with distortion??

12 dB SINAD means what? The signal is 12 dB greater than noise and
distortion or
is it more complicated than that?

Yes, that's exactly what I said in the other posting. But some
people seem to believe that inserting a Bird into a transmission
line with a Z0 other than 50 ohms magically changes it to a 50
ohm environment. The 40mm of transmission line inside the Bird
is supposed to accomplish that miracle.

This fiction is entirely your own invention and trying to put Owen's frame around your cartoon does not elevate this nonsense to art.

You have done nothing to offer any substance to your claim except the time worn tradition of repetition, deflection, and ignoring the observables by insisting error exists where it is not.

What reflections exist, exist at the input port of the Bird which is 50 Ohms by design, and which is attached to a 50 Ohm load by deliberate selection. The Bird's response confirms the load, and the rest stands on 50 years of Bird quality construction (he's not using the poorer model with PL-259s).

Owen's work stands on its own, despite your chatter of a nabob of negativity (apologies to our ex-VP-ex-convict of the GOP).

Sorry, I am just quoting Owen's results. There was 4.1667 watts
of reflected energy flowing back through the Bird. The Bird
indicated zero watts. That's an infinite percentage error on
reflected power for the Bird and proves my point that a 50 ohm
wattmeter used in a 75 ohm environment is like using a hammer
on a screw. To paraphrase: when the only tool one has is a 50
ohm Bird, every Z0 environment looks like 50 ohms.

But the 50 ohm load is attached through a piece of 75 ohm coax
supporting an SWR of 1.5:1. If you don't realize that fact, I
feel sorry for you.

Thats about it.

It is the ratio of signal to noise and distortion, and it is measured by setting up a test where the receiver produces output from a SSG (typically for a 1KHz audio output) and notching out the 1KHz output to measure the noise and distortion wrt the filtered 1KHz output.

I wrote a handy little calculator for converting rx senstivity metrics, it is at http://www.vk1od.net/sc/RxSensitivityCalc.htm . The conversions assume that the signal distortion component of the Noise+Distortion is zero, in other words that the demodulation and amplification process is linear.

SINAD is used widely to express the sensitivity of AM, FM and SSB receivers. It is a much better method of measuring FM receivers than the older "quieting" measurement.

The bottle was chosen at random by my daughter from the supermarket
shelf. Following your message I retrieved it from the trash bin.

The label did not mention a 'drink by' date. But it does mention eat
with a mature blue cheese which is a firm favorite of mine. I've long
given up worrying about cholesterol.
==================================
>
> IIRC, the labels carry a bit of a story on their wildlife refuge, do

==================================
Yes. I looked up Banrock Station's website about their contributions,
internationally, towards preservation of wetlands, nature reserves,
and the many forms of wildlife therein. There's even a photograph of
a water snail. Very interesting.

I guess you are far more knowledgeable about wines than I am. Thanks
for drawing my attention to the bottle.

Unless you need the retracting feature, don't fool around with those baby poles and buy one of the mothers featured at
http://www.excelsails.com/flagpole.htm
If you buy one of their 40 feet models, you get a rustic rod with a butt diameter of 5.25" tapering to 2.5" at the top. Compare this with the puny wonderpole's dimensions of 2" and 0.75" respectively.

Cec,

I have tried to avoid entering this argument.

But it appears to me that ALL SWR meters work on the principle of a common, identical, take off point for both voltage and current samples.

Therefore, anything inside the meter which could constitute a transmission line, no matter how long or short, if it separates the two effective take-off points, it is a small source of error and its actual length otherwise plays no part in the measuring process.

(I mean its actual length is not included in the basic design calculations, except perhaps in rare instances to minimise the error.)

(The error arises from a phase-shift error in tapping off the current sample. There may be no problem with defining the location of the voltage sample. All depends on meter construction and the tapping methods which vary but do not affect the basic design principle of a common tapping point.)

I am not trolling. Please read very carefully. Try to limit yourself to HF and VHF. Do you agree? Yes or No?

Reg, G4FGQ.

Hi David,

So I noticed on the patent papers. I also noted the assignee is in
Half Moon Bay. When I was a kid I lived a few miles north of there in
Pacific Manor, later changed to Pacifica, and probably now aggregated
into some megopolis - if the cliffs haven't dissolved away to leave it
in the surf (Highway 1 used to slip beneath the waves with each minor
earthquake - we were only a mile or so from the San Andreas).

It is the ratio of (Signal + Noise+Distortion) to (Noise+Distortion) as measured at the receiver audio output. It is measured using an RMS-reading AC voltmeter , typically with a 1Khz modulation tone on the signal applied to the receiver under test.

First you measure the audio signal out of the receiver using the AC RMS meter. Then you apply a notch filter at the modulation frequency and measure the residual noise+distortion, again using the RMS AC voltmeter. SINAD is the ratio of the two measurements.

>

That should be:
It is the ratio of signal and noise and distortion to noise and distortion, and it is measured by setting up a test where the receiver produces output from a SSG (typically for a 1KHz audio output) and notching out the 1KHz output to measure the unfiltered output wrt the noise and distortion.

I should also have mentioned the EIA test requires the receiver be set to rated output with 1mV RF input at 60% of rated modulation, then the RF output reduced to find the input level for 12dB SINAD.

You could measure it with soething like a HP334A Distortion Analyser, but it is pretty tedious if you are trying to find the RF input for a particular SINAD. Hence you see boxes that have an AGC controlled amplifier deliving a constant voltage to the filter block. I have a Motorola one (R1013A) that works ok, there were also Sinadders. Even more convenient are the ones integrated into a communications monitor. I don't believe these boxes do true RMS measurements.

An alternative if you have a standalone SSG and want to do SINAD measurement is to use a PC sound card and software that does an FFT and calculates the SINAD (using true RMS measurement). Spectrum Lab does it, its free, but it is such a flexible / general tool, it may be a bit daunting to get it working. The SpectrumLab menu "Quick Settings / Rx Equipment Tests / SINAD test" is a quick path to setup... but it is still a quite complex package. A whole lot better than the style of a HP334A though! SL is at http://www.qsl.net/dl4yhf/spectra1.html .

and what the experiment pointed out was that the length of feedline attached
is immaterial, the 50ohm environment is established within the meter itself
and it doesn't care what the length of feedline attached is.

yep, that is true, and that is what the experiment shows. the 50 ohm load,
even though it is caused by a 75 ohm line, is far enough away from the
sensor that it sees it as 50 ohms. so the 'miracle' length is obviously
less than 40mm.

ah, but the sensor isn't in a 75 ohm environment, it is in a 50 ohm
environment inside the meter and sees a 50 ohm load.

The SWR on the 75 ohm line is 1.5:1. If 100 watts is delivered to
the load, there's 4.1667 watts of energy reflected from the load
and flowing back through the Bird. The Bird doesn't see it because
the Bird is calibrated for the wrong Z0.

Really? They why bother with characteristic impedance at all?
If Z0 doesn't establish a Z0 environment, then all transmission
lines are just alike and transmission theory is hogwash.

There are a number of different designs. One very popular class of
designs samples the voltage and current essentially at a point. If
the device is in a 50 ohm environment and the two samples are equal
in magnitude and phase, there is no reflected power. If the device
is in a non-50 ohm environment and the two samples are equal in
magnitude and phase, reflected power exists at the sample point even
though the device reports none.

All of the above is why this class of wattmeters, including the Bird,
does not establish a 50 ohm environment merely by being inserted in
a non-50 ohm system. The Bird samples voltage and current essentially
at a point, assumes it is in a 50 ohm environment, and reports the
power reading. If it is not in a 50 ohm environment, the power reading
that it reports will be wrong as Owen's experiment proved.

> and it doesn't care what the length of feedline attached is.

The experiment proved that the 50 ohm environment is NOT established because the Bird readings were wrong. The Bird reported 100 watts forward power where the actual forward power was 104.1667 watts. The Bird reported zero reflected power where the reflected power was 4.1667 watts. Thus the experiment proves my point. The Bird does not yield accurate results when embedded in an environment other than 50 ohms.

All the Bird does is sample the voltage and current essentially at a point. If the ratio of net voltage to net current happens to be 50 ohms, the Bird will report a matched condition, no matter what the Z0 of the transmission line and no matter how much reflected power actually exists at the measurement point. For instance:

XMTR--balun--1/2WL 450 ohm line--x--1/2WL 450 ohm line--50 ohm load

The SWR on the line is 9:1. The reflected power is 64% of the forward power. If forward power equals 100 watts, reflected power will be 64 watts at point 'x'. Yet a Bird wattmeter inserted at point 'x' will read zero reflected power. The environment is clearly 450 ohms. The reflected energy doesn't tuck tail and run away when the Bird is inserted. The Bird is simply giving the wrong reading for reflected power because all it is looking at is voltage and current at a point. This is such elementary transmission line stuff that I cannot believe there is any argument about it.

The insertion of a Bird wattmeter in the middle of a non-50 ohm environment does NOT eliminate the reflected energy that exists before the insertion.

So a one inch piece of 50 ohm coax forces the ratio of net voltage
to net current to be 50 ohms? Of course it does. You had me going
there for awhile. I didn't realize until now that you were pulling
my leg all the while.

Again, 40mm is not enough to establish a 50 ohm environment
when embedded within a 75 ohm environment. The Bird is simply
sampling voltage and current without knowing the reference.
If the Bird were recalibrated for 75 ohms, it would read the
correct values in a 75 ohm environment.

ah, but if the bird does establish a 50 ohm 'environment' within its 40mm
housing then the reading that was actually obtained is indeed correct. so
now, how else could you read zero reflected power at that point if it didn't
establish that environment? what other evidence to you have that 40mm is
too short? if 40mm is too short then why do we worry at all about impedance

bumps in connectors that are 20mm or so long??? if 20mm is enough to see a bump then that is obviously affecting the 'environment' on the line.

yep, sounds good to me. now, someone please put a bird meter on a tdr and
see what the characteristic impedance of it is internally. then put it on a
network analyzer and see if it does indeed transform the 'environment' from
75 to 50 ohms in its 40mm length. oh and while you are at it calculate the
s factors for all the transitions, those will come up in the discussion here
shortly.

> housing then the reading that was actually obtained is indeed correct. so
> now, how else could you read zero reflected power at that point if it didn't
> establish that environment?

Would you like for me to go through the math of a voltage and
current sampled at a point without disturbing anything?

Assume the voltage is sampled such that 100v of net voltage
is sampled as 10 volts.

Assume the current is sampled such that two amps of net current
is sampled as 10 volts.

If these samples are in phase, adding them will result in 20v.
That equals 200 watts of forward power on the meter.

Subtracting them will result in zero volts. That equals zero
watts of reflected power on the meter.

The sampled net voltage and net current determine the 50 ohm
calibration. No 50 ohm environment required.

If the sample point is in 75 ohm coax with no reflections, the
sample voltage will be 12.3 volts and the sample current will
8.165 volts. Subtracting those sample values doesn't yield zero
so 41.35 watts of reflected power will be reported where none
actually exists.

So unless the mere writing of my words on this newsgroup
establishes a 50 ohm environment, the Bird doesn't need to
establish a 50 ohm environment to obtain the same above
results.

If the Bird indeed did control the environment into which
it was inserted, it would be violating a design goal for
measuring instruments and Bird wouldn't be selling many
of those highly intrusive devices. Bird wants the meter to
be as unobtrusive as possible and it is.

Probably all that is needed is to measure the Bird's s11
parameter while sitting in a 75 ohm environment. I'll
bet it's very close to zero.

The recent MFJ catalog contains several new loop tuners. These seem almost too good to be true, given the wonders of "small loops" discussed many times in this newsgroup. Has anyone tried these new products?

Also, MFJ has a new Clamp-On RF Ammeter (calibrated for .3, 1, and 3 amps) for only $50. Any thoughts -- might it be useful for measuring currents in radials (just to verify that each radial is doing something!).

who says an instrument can't control it's environment? and who makes that a design goal?? and who are you to say that bird wanted to make the meter 'unobtrusive'?? every instrument has some loading or effect on the circuit it measures, some more than others. some even include 50 or 75 ohm loads internally to load the circuit they are attached to. Ones that pass a signal through their own sensing circuit often have more of an effect than others.

It was previously reported that the path through the Bird
is 40mm. The path through the Bird is actually about five
inches which is probably long enough to establish a 50 ohm
environment.

Dave,

Goto http://www.uspto.gov, then do a search for patent # 06603440 ---
you will need a viewer installed (quicktime works for me) to view images.
Also, I have noticed some problems using Firefox when trying to view
images on US patent office site, so use Internet Explorer.

If you manage to get it working, check out the snowflake antenna on page
3-4.

Good info, Owen. I think the EIA test procedures really have FM or AM in mind, rather than SSB or, what is exactly the same for SINAD purposes, CW. The 60% figure just doesn't apply to SSB or CW. You would simply use an unmodulated signal generator with the frequency offset to produce a 1 kHz tone in the receiver's audio output, preferrably centered in the receiver's passband. Then a measure of rms af voltage at the receiver's output with and without the 1 kHz filter would be made.

We don't hear much about SINAD testing procedures for SSB and CW. Even the ARRL's test procedure manual glosses over the procedure for other than FM.

Richard,

HMB is still a fairly small town, and Hiway 1 on the cliffs south
of Pacifica still falls into the Ocean on a regular basis. That
is why they are now building a tunnel through the coastal
mountains (even closer still to San Andreas fault) between
HMB and Pacifica. It remains to be seen which will be worse,
the eroding cliffs or the collapsing tunnel. lol

SINAD measurements were cooked up because the audio quality of an FM
receiver depends both on the demodulator and on the noise
characteristics of it's front end. Just having a noise figure for an FM
receiver is pretty useless. Keep in mind that an FM receiver is usually
rated as "X dB SINAD for y microvolts input".

For SSB and CW, on the other hand, the noise is purely additive so all
you need to know is the receiver noise figure. Once you know that
(assuming that it's not a really strange radio) you know everything
about it's performance. Given the noise figure in dB you can easily
calculate the 12dB SINAD should you be so inclined, as well as any other
signal vs. noise figure you should want. You have a good reason to
believe that the noise is white so you can even take an SSB receiver and
calculate the noise figure of the thing after you tack on an audio
bandpass filter for CW. This is _not_ the kind of thing you could do
with FM.

Specifically, the "miracle length"is 0. My SWCad simulation assumes 0 length
interconnects, 0 spurious capacity, and 0 spurious inductance. Also, I might
add, near infinite bandwidth. In fact, it should work at DC. Haven't tried
that, but it works the same at 100 Hz as 100 MHz.. It gives generally
accepted answers.

Owen, (& crb)
Your words are contrary to the way we measured it (Motorola). You say
..."It is the ratio of signal to noise and distortion,..", but we measured
not just the signal, but everything for the "top" of the ratio (which is
used more like a reference as it is the more stable as signal level varies).
I believe your last line saying wrt to the filtered tone supports this. It
implies that the tone is (bandpass) filtered for one of the measurements and
we don't do that.

Joe's is a bit better of an explanation (the RMS meter and quantities
ratioed).

A meter, a pure 1kHz tone modulated signal generator and a 1kHz notch is all
that is needed. What happens if you don't have a "real" RMS meter? I don't
know.

How amusing.

This dovetails with your own proof (sic) - HERE - how the Bird has failed to sense that very lack of cancellation looking into a quarterwave section that offers a perfect match to the Bird. As I said, you lost your logic on the first bump in the road you took.

This is an amusing irony of where you have found power where you have always posited there is none, and where you have rejected there is power when it has been shown to exist. Each example exposes your lack of experience in the scale of the error and its relation to the equipment measuring it.

And both times it has come at the topic for which you have absolutely no experience with at the bench. Your arguments are exhibits of the failure of third hand-off quotes bolstered by Xeroxed citations. They all come out of books that are suitable catechisms for puttering students and doddering intellectuals, and they fail in the face of obvious results demonstrated at the bench.

Of course, this is advanced topics I am speaking of when we get to the reality of actual results, and no doubt it shakes your Sunday school sophistication of faith in a comic book level of practice.

I will now leave you with your sputtering attempt to recover. ;-)

>guess the v/i discussion is over now.

Hi Dave,

It may have been tailored in that vernacular, but it was actually never about that at all. As the last "thin-film" comment reveals, it has always been about how one mind can encompass two contradictory positions (total cancellation - non total cancellation) about the same mechanism (a quarterwave matching section).

In other words: A Troll.

The humor here is that supposedly the thin-film offers "total" cancellation for the same reason that the quarter wave from this bench test does not. :-)

In fact, neither exhibit "total" cancellation, but to maintain the charade one or the other does, then that charade must fail, and these recent arguments have just revealed that fracture.

Some time ago I offered results from the bench in just how much light was in fact returned from a thin-film section, and this was rejected as impossible - hence the allusion to brighter than the sun light being rendered as black to satisfy this illusion of "totality" in cancellation. This reflected light was buried in the digits, but still and all, far brighter than the sun (such is the vast range of accommodation that the eye offers as a measuring device).

On the flip side, any leakage (reflection back) from a quarterwave section suffers identical issues. Those reflections are buried in the digits too. This is orders of magnitude different from the speculated 4.17 watts which is a farrago. Does a Bird have the same scope of resolution as the eye? Hardly. The inherent error of the meter at ï¿½5% vastly overwhelms such products (the eye does not suffer such error for other reasons - imagine what a driver's eye-check test would be like if it did).

So, to advance this itinerant concept of Owen's demonstration not busting the myth of the requirement for line sections, this troll has diverged from the topic to haul out a spurious argument that is in direct conflict with other discussions of the same topic, from the same troll. It necessarily demands a villain to suit the melodrama offered. That villain is the Bird and its failure is to reveal a power. Left unsaid is that actual power is, as I said, buried in the digits and wholly irresolvable. Further, it is NOT the claim of 4.17

watts which was rummaged up. The Bird would be incapable of resolving the actual reflection products from a real quarterwave section. Thus it cannot absorb the sin of this counter-proof (sic).

Let's just say that statements that arbitrarily assign ideal concepts like "totality" suffer across the board - and when these forced assignments are used as the link pin to "theories," then they can lead to amusing contradictions and failures of logic like those we've been witness to here.

I think it might also be interesting to discuss the instance in which
the Bird is interfaced with a real halfwave section.

Hi Steve,

You don't need a "real" RMS meter. The expressed requirement for a
pure 1kHz tone provides the necessary sine wave shape such that it
simply becomes a matter of scale calibration. If you had said a
square wave 1KHz tone (nothing pure about that), then you would have
to dig deep for a "real" RMS meter. That too, could be scaled, but I
wouldn't count on it because it would be a rare amplifier chain that
could faithfully keep it square - and the notch would inject it into
the measurement as distortion and noise.

Owen wrote:

"The myth that measurements with a Bird 43 of conditions on the Thruline section are invalid unless it has some minimum length of 50 ohm line on both sides of itself is busted."

Bird says the wattmeter can be placed anywhere in the line. That precludes a requirement to have minimum lengths of 50-ohm cable on both sides of the wattmeter. Particular total lengths of line woould be a function of wavelenth.

The Model 43 Thruline Wattmeter accurately measures forward or reverse power in transmission lines under any load condition.

Regardless of the load impedance, the forward and reflected powers are forced by construction of the coax to conform to Zo. Line volts divided by line amps in either direction has an absolute value of 50 ohms.

Bird plug-in elements are designed for insertion into a precision coaxial rigid air line which is a part of the Model 43. Elements are available in a wide variety of frequency ranges and maximum power levels..

Cancellation of response to one direction of power flow while responding to the to the other is accomplished by careful balance of the current and voltage samples within an element. The samples which are in-phase add. The samples for the other direction are out-of-phase and cancel.

To make sure cancellation is complete in the undesired direction, Zo must be as specified in the design. Accuracy can`t be expected in the wrong Zo environment.

Best regards, Richard Harrison, KB5WZI

In exactly the same way that forward power can exceed generated
power in a 1/4WL matching section of transmission line, so can
the forward irradiance in 1/4WL of thin film exceed the forward
irradiance in the air before incidence. That you are still so
terribly confused about such a simple fact of light physics is sad.

If the incident irradiance is a single frequency coherent signal,
the requirement for TOTAL CANCELLATION OF REFLECTIONS is still
that the index of refraction of the 1/4WL thin-film be the square
root of the medium upon which it is deposited. QED

Richard,
What you said is largely accurate, however at low S/N ratios, or where the distortion becomes comparable to the signal level, the reading of the composite signal (signal+noise+distortion) with anything other than an RMS meter could produce erroneous results.

It was a shabby description in my first post Steve, I wrote filtered
instead of unfiltered, had the "wrt", terms back to front at the and,
as you quoted signal to (N+D) when it is the total to (N+D). Wasn't
really worth 2/10, was it! I re-read it when I came back to add some
detail re a software approach and redrafted it.

My recollection was then when the scheme was introduced, one used a
Distortion Analyser, and I can't remember the early HP instrument, the
HP334A I mentioned in my follow up was a newer one. They are tedious,
whereas the R1013 or Sinadder or much more convenient, and the
integrated ones (like in the R2000) are much better.

Once you sort the issues of getting audio samples to a PC sound card
without hum and clipping, that approach can work well, and Spectrum
Lab works well... just it is a multipurpose tool for a simple job.
There are probably other software tools that are more targetted and
simpler to use.

>
>Joe's is a bit better of an explanation (the RMS meter and quantities
>ratioed).

Yes, but I don't believe most of the instruments acutally incorporate
a true RMS meter. I set about measuring the difference about six
months ago when I was doing calibration / validation measurements for
FSM (http://www.vk1od.net/fsm/) using custom software against the
R1013, and R2000, and a couple of HP334As. The error in using a
rectifier-average responding meter (as is typically done) is small
relative to the variance of such readings because of the variance of
the noise component.

>
>A meter, a pure 1kHz tone modulated signal generator and a 1kHz notch is all

>that is needed. What happens if you don't have a "real" RMS meter? I don't
>know.

Yes, I didn't mention that the 1KHz tone needs to be relatively low
distortion. For measuring 12dB SINAD, the demand is not onerous, but
it is important. The frequency of the tone is important as the notches
in semi automatic instruments are typically +/10Hz or so, so one needs
to verify that the SSG modulation oscillator is close enough. More
importantly when testing an SSB receiver (where you use a CW carrier),
that the carrier is kept "on frequency" for a 1KHz beat note.

Cecil,

If you are referring to my statement in another thread, it was that the sampling element is about 40mm inside the 50 ohm Thruline section (ie that there is about 40mm of 50 ohm transmission line between the Bird 43 terminals and the sampling element), not as you have stated above.

If the Bird is inserted at a point where the net voltage divided
by the net current is equal to 50, apparently a 50 ohm Z0-match
is achieved at that point and any length of lossless 50 ohm coax
can be inserted without altering the forward/reflected conditions
in the adjacent transmission lines.

I'm sorry, Owen, I took your statement to mean that the total length
of path through the Bird is 40mm (1.5") which is not enough length
to force a 50 ohm environment. I downloaded the Bird manual this
morning and discovered that, unlike an MFJ, the path through the Bird
is about 5 inches and coaxial. I apologize to Bird and you Bird
experts for that bad assumption.

That explains why my new tuner failed to work. I have a rotary switch that selects 40mm of 50, 75,300, 450, and 600 ohm coax. I thought it should match anything! Now I see I have to go to 5" lengths. I should know better than to build anything before all the errata sheets are in.

I can use some additional diversion as almost all the soldering iron burns have healed.

All,

Can I offer the suggestion that the key to understanding why this is so, it to understand the sampler.

I don't have the detail of the physical and electrical parameters of the Bird sampler, however I suspect that like so many other reflectometers, it comes down to a device that samples independently the net current and the net voltage associated with any travelling waves, and those RF samples are in proportion and phase relationship that when algebraicly added and rectified, they produce a DC voltage that is proportional to the power flow in one direction only (provided that Zo is real). The proportions calibrate the instrument for a specific V/I ratio.

Apart from mentioning that Zo must be real, and I will address that in another thread, Zo in the region where the sample is unimportant to the "proportion and phase relationship..." bit. Zo of the through line is important only to the extent that you would generally:
- not want a significant transformation of impedance between the load terminals and the calibrated sensor at that calibrated V/I ratio.
- not want a significant transformation of impedance between the generator and load terminals at that calibrated V/I ratio to minimise disruption to the system being measured.

Everyday we use instruments to measure something, somewhere and apply that knowledge to infer something else, somewhere else using appropriate other knowledge. For example, you might measure the voltage drop across a cathode resistor and make some reasonable inference about anode current using appropriate other knowledge. Making measurements with a Bird 43 in one place and inferring the situation somewhere else using appropriate other knowledge is reasonable.

For example, I may have an antenna system (say a loop) that uses a transmission line transformer (TLT) to transform the loop terminal Z to 50 ohms. I can attach the generator end of the TLT to the Bird 43, attach the Bird 43 via 50 ohm cable to a transceiver that is rated for a nominal 50+j0 ohm load, and proceed to adjust the antenna / TLT for

zero reflected power indication on the Bird 43 knowing that I can reasonably infer that the load presented to the transceiver will be approximately 50+j0 ohms using the knowledge that Bird readings indicate Z at that point is 50+j0 and there will be insignificant transformation on the 50 ohm cable to the transceiver. This is a proper and sound application of the instrument.

Did I get that wrong?

Did I need to mention environments?

Hi Joe,

In the practical world of SINAD (having tuned a number of GE and Motorolas), one is not very interested in how poor your set is, but rather meeting a service standard (that 12 dB which is as arbitrary as any).

I doubt if many of the current generation of commercial surplus equipment comes with a stock tester employing what would have been an expensive converter chip to insure RMS measurements. I come by that assessment by noting those I used employed standard meter movements. The first RMS meters I calibrated in the mid 70s came from Fluke (just up the highway), and the components of that circuit were scrubbed of all identification numbers or cast in epoxy. Such was the cachet of being hi-priced, and having others try to break into the market with knock-offs.

My Radio Shack multimeter makes that claim (ca 1995) and if memory serves, that Micronta's "True RMS" was barely capable of poor voice grade bandwidth. This was 20 years after Fluke, costing about as much (economic inflation), and not performing as well (technical deflation).

>with FM.

Indeed Tim. The complications as I see it in predicting the SINAD for FM when you know the receiver NF is that most narrow band communications applications of FM are closer to PM because of the pre-emphasis characteristic.

FM + 6dB/octave preemphasis over the entire modulation passband is PM. (PM is where the modulation index (dev/fm) is independent of fm (the modulating frequency)).

However, the receivers in my experience are over de-emphasised (at the top end) presumably to get better SINAD. In fact, I think specifications of the de-emphasis curve are commonly stated along the lines of +1 to -3dB of -6dB demphasis relative to 1Khz over 300 to 3000Hz. This accomodates a over de-emphasis at the high end for little loss in intelligibility and a dB or so improvement in sensitivity figures.

Filter / demodulators and CTCSS IM also contribute to distortion products significantly.

The result of demod distortion, PM with a slope across the passband, and uncertain high pass filtering to accomodate CTCSS makes prediction of S/N out from C/N in a bit of a guess in FM comms receivers, not nearly as accurate as you suggest for linear receivers.

Cecil, With a 1/2 wl of 75 ohm line terminated with 50 ohms at both
the source and load end, the 4.17 watts reflected energy does not flow
back thru the Bird. With 100 watts incident on the source (Bird), 100
watts will be either radiated, or consumed as heat at the load end.
4.17 will be reflected back to the source. When it reaches the source,
a portion will be reflected back towards the load, and a portion
consumed as heat. ect. The small portion consumed by heat might
account for the 1/2 needle deflection Owen observed on reflected power.
4.17 watts does not flow back thru the Bird as reflected power, and
the Bird, of course acknowledges. I don't think the Bird ignores that.
I acknowledge that the Bird does not report the actual forward/reverse
power in this example

Hi Gary,

And none but one does.

> I acknowledge that the Bird does not report the actual forward/reverse
>power in this example

And this responds to a fabricated question.

Who would approach a Bird and expect it to in the first place? A lid.
This is like complaining that your speedometer doesn't report the
actual speed of the car passing you. Having said that, an entire
thread of correspondence could grow to show adapters and cables
between the two cars "could" contrive to make that happen, and then
the topic drift would blame the erroneous name of speedometer, when it
is only a highway-to-tire traction indicator - HTTTI.

If I were back in the calibration business, this stuff would be like
gold being pushed across the counter.
"It doesn't work when I put it into an out-of-spec system,
could you check the accuracy against a known load?"

I suppose most of the filthy lucre has been absorbed into either Iraq
or FEMA contracts.

I did not report or even measure such a thing.

It is your report based on something that you know or something that you measured without evidence of either measurements or detail of construction.

With respect Cecil, the statement is more an elaboration of the myth than convincing support for it.

This unsubstantiated premise seems the basis for nearly a hundred posts by many.

Richard,

I understand the historical difficulties of making accurate RMS measurements, however I didn't know the original post only solicited ways to make the measurement with "current generation of commercial surplus equipment ". My intention was to point out some measurement nuances that might not be obvious at first glance.

Recently, it has become quite easy to do true RMS measurement at audio frequencies using DSP techniques. In fact at audio you can even do an accurate RMS measurement in DSP using a PIC microcontroller to sample the signal and perform the calculations.

Originally, two way shops set FM rigs up for 20 dB quieting, on a volt meter (crank up the signal until the AUDIO VOLTAGE, UNMODULATED, was 1/10th the voltage of a no signal audio output . Tho, for the most part, this works well, there are constraints on sensitivity, because of bandwidth concerns, and , as bandwidth is halved, the signal improvement is 6 dB (quadrupled). Sinad is Signal/Noise /signal/(noise+distortion) and in fact, in recent times , devices that will measure it are built into many pieces of test equipment (IFR meters comes to mind), also look for an outfit called "SINADDER" . The main thing is that it adds a "Bandwidth" component to the sensitivity equasion. It is measured with a 1 KHz tone, at (in FM), 3 KHz deviation- and the smaller the signal that is detectable , with this constraint, the more sensitive the reciever is considered to be! This also works at SSB/AM. Tho, it is true that this measures Sensitivity, it includes a BANDWIDTH component, that a (noise figure/ quieting) would NOT consider (at least fully!) Hopefully, this is helpful-- Jim NN7K

A visit to:
http://grc.com/default.htm
will resolve ALL issues of security that have originated from the
clown act of Windows sicurity development.

I've been on the web with Windows, without their updates for a decade,
and having observed all the cautionary tales and prescriptions and
tests offered at this web site above and I have endured EVERY mishap
that has come down the pike - and no failures or lost files.

I recently installed Win2K on a new laptop, and made the mistake of
attaching it to the Web to visit that web site, and within 10 seconds
I was under attack (messenger). I pulled that plug, and did my tests
by transferring all the executables from Gibson and Agnitum (firewall)
by Flash Drive between computers. That snuffed those suckers out.

My firewall alerts me to attacks like bugs hitting the zapper on a
summer evening. I take their IP and look them up for amusement.
Tonight I've been probed by Taiwan and Turkey and my firewall had them
standing in the queue, hat in hand like tradesmen at the back gate.
They will starve first before my system will even give them so much as
a handshake.

Now for the question of the day:

Does anyone want to really talk about fractals, or simply spit on
them?

Hi Joe,

That was interjected by me, knowing the market of the past several
years being flooded after trunk systems began replacing older service.

>My intention was to point out some measurement nuances that

Yes, the miracle of Moore's law. 20 years ago I was with HP, here, to
help them introduce their 100KHz real-time dual channel audio spectrum
analyzer. That was a tremendous effort with a million lines of Pascal
code and 5 years in the making when most HP instrumentation hit the
market in 18 months from inception.

I got to know the range of FFTs under some of the most brilliant minds
on the topic. One, Nick Pendergrass, went on to teach at an eastern
university.

Today, it is an underclass topic, probably occupying no more than 6
weeks of instruction coupled to other interests. Still and all, I see
considerable errors of omission in the discussion. Such errors often
make the difference in delivering a serviceable performance compared
to that which is 100 times better (actually a million times, but few
could get their imagination around a number that big so I understate
it).

Again Owen, your own experiment using 75 ohm coax on each side of the Bird proved why the above is not a myth. The Bird didn't read the correct forward power on the 75 ohm coax. The Bird didn't read the correct reflected power on the 75 ohm coax. The SWR calculated using the Bird's readings does not represent the SWR on the 75 ohm coax.

> The proportions calibrate the instrument for a specific V/I ratio.

Yes, that ratio is 50 ohms for the Bird. Only a piece of 50 ohm coax will guarantee that Vfor/Ifor=Vref/Iref=50 ohms. You proved that a piece of 75 ohm coax will not do it.

> Did I need to mention environments?

No, but you should have. The Bird gives the correct forward and reflected power readings on the attached coax only in a 50 ohm environment. Your experiment proved that to be true.

jgboyles@aol.com wrote:
> 4.17 watts does not flow back thru the Bird as reflected power, and
> the Bird, of course acknowledges.

Yes, I later realized that the Bird's internal feedline forms a
50 ohm Z0-match. Interference at the input and output of the Bird
causes no reflected energy to flow through the Bird. The reflected
energy from the load is re-reflected at the Bird output. The input
of the Bird causes reflections on the source side of the Bird. I
actually calculated all the interferring signals.

> I acknowledge that the Bird does not report the actual forward/reverse
> power in this example

That was the main point. If the Bird is embedded in something other
than a 50 ohm environment, it does not report the actual forward/reverse
power on the coax on either side of the Bird.

Since I realized the Bird forms a Z0-match at its output that
statement should be ammended to say: There 104.17 watts of forward
energy flowing in the 75 ohm coax on each side of the Bird and 4.17
watts of reflected energy flowing in the 75 ohm coax on each side
of the Bird. Why does the Bird ignore those actual power values
existing in the actual system?

100W--tuner---75 ohm coax---Bird--1/2WL 75 ohm coax--50 ohm load
Pfor=104.17W--> Pfor=104.17W--> 100W delivered
<--Pref=4.17W <--Pref=4.17W

The Bird is not reading the proper values of forward and reflected
power on the 75 ohm coax because it is embedded in a non-50 ohm
environment.

This has nothing to do with the stated myth: Measurements with a Bird 43 of the conditions on the Thruline section are invalid unless it has some minimum length of 50 ohm line on both sides of itself.

Nothing in the myth stated or implied direct application of the measured conditions on the thruline section to any other connected (or disconnected for that matter) transmission line, that is entirely your construction.

It is a diversion Cecil.

Owen

Still not sure what it is.

I know I do a test at work where I put in a 3 KHz deviated, 1 KHz tone into the FM receiver
port while probing an audio point going to the SINAD port on the test equipment.
Increasing the input level makes for a larger SINAD value (which makes sense)
Looking for at least 12 dB SINAD.
What is so special about 12?

Can't get my mind around it. Is the test tone 12 dB stronger than noise + distortion?

Is the the input value in dBm on the test equipment the sensitivity of the receiver at 12 dB SINAD.
The 'at 12 dB SINAD' still gets me.

I was seriously thinking of plunking down the $250 plus for the 40-foot
Wonderpole (www.wonderpole.com) to support parallel dipoles (probably
14
gauge stranded copper wire dipoles cut for 80, 40, and 20 meters), fed
with
600 ohm open wire, but I am concerned about: .....

Dunno. Costs too much vs a standard push up mast, unless it
lets you avoid guys, and I sorta doubt that being the metal mast
does require them. The antenna wires can guy the top, but you may
need a set of mid point guys. Another problem...I prefer a metal
mast as far as a lightning return. I've taken strikes, and never have
a
problem with the metal masts. I assume a glass mast would be toast
unless you ran wires down it as a lightning return.
The only advantage I could see is it's non conductive as far as rf,
but in the real world, I've never once had a coupling problem from
using a metal mast to support wire antennas.

It is probably a good enough ratio to express the lower limit of
usable sensitivity for telephony applications.

If you mean why isn't it 11 or 13dB, it may hark back to the early
instruments that were intended for measuring THD and were scaled in %
distortion. 12dB SINAD corresponds to 25% distortion on such an
instrument.

Thanks. There were some other typos along the way, but that was
clearly a spelling mistake and the spell checker didn't find it.

>Interesting thread though. BYW, is the Bird using the Bruene type bridge

Is that BTW?

I understand that the Breune type bridge is one of the bothways
detector designs with a untapped toroidal current transformer. I doubt
the Bird sampler element is of that type.

It appears to have a flat section of line that is parallel to the coax
centre conductor and is presumably capacitively and inductively
coupled, and it uses some form of frequency compensation to give it
broadband response. You rotate the sampler element for measurement of
the opposite direction.

Someone here may have dismantled one to see how it works.

I suspect that all of these probe designs try to sample net V and I at
a point, and the extent by which they depart from a point sample
limits their upper frequency of usefulness.

Though there are several designs, they seem to broadly fall into two
main types, those where the sampler response is inherently
proportional to frequency (though they may be compensated as in the
Bird elements) or those where they are inherently broadband (as the
Bruene circuit).

Trust you are well. I heard you on 40m the other day, but only just!
Propagation has been pretty shabby.

Source record: 68809

After 36+years in the radcoms industry as a technician I have seen the move from S/N to SINAD at first hand.

SINAD has been around throughout my career but it is really on in the last 20 years that it has become most prevalent. The only reason that I can think that this has become so is the improvement in technology in the production of semiconductors and the consequent reduction in their noise levels, and the much wider use of FETs in front ends, which has resulted in S/N becoming an unrealistic measurement, the noise floor now being so low. Add to this the now commonplace use of SMD - which itself is 'quieter' - and improved circuit design, and the distortion in the modulation becomes of significantly greater importance.

Having said that 10% distortion was the norm when I started, whereas 2% or even less is today's standard, such are the improvements in that side of transmission, hence SINAD is probably now the only viable measurement.

Think of it like this: in the mid 70's most receivers would do 12dB S/N for around 0.6uV for 60% system modulation on a 12.5KHz channel spacing; today it is not uncommon to see 12dB SINAD (let alone S/N!) at not much above 0.2uV, and if you look at equipments of far eastern origin which may not have such good parameters (selectivity, adjacent channel rejection, etc) as UK/European designed units it can be 3dB better than that! Perhaps that's why you see a lot of oriental mobiles and portables but most associated base stations, especially those used on communal sites, are designed or made elsewhere (UK, USA, Germany, and New Zealand to mention but a few.)

Why 12dB? My two penn'uth is that the human ear is very tolerant of even harmonic distortion, especially 2nd which would predominate in the audio chain due to filtration, so someone somewhere defined 12dB (or about 25% distortion) as the maximum tolerable level for usable speech.

Just thought I'd update on my progress.
First off, I am 'Fedthecat' but I got a new email adderess so now I'm 'sofasurfer'.
Still haven't got AM to come in at work. But, I have some observations and clues.

1. I now have a differant boombox that has a moveable external AM loop and external AM (as well as FM) connections. This radio DOES get AM quite well outside the building. Also cars parked outside, 10 feet from where I put my antenna receive AM, therefore there IS a signal available.

2. Many people at work say that they've tried to get AM and all have found that there is no way to get AM in a steel building such as a GM plant.

3. One guy even tried differant types of antennas on the roof. But no signal would reach his radio inside the building.

4. The best I get is 760 AM, very fuzzy, barely understandable. 950 AM is worse. Those are the only two stations coming in at all. They do not fade in or out.

5.One day as I was fiddling with the wires on the back of the radio AM suddenly came in loud and clear with no static for about 1 second. I was unable to repeat this and that makes no sense to me.

6. I am concerned about my ground, although the 1 second clear signal tells me I have a good ground. The antenna is grounded to the chain link fense post which is set in concrete. Is concrete conductive to the ground or does it insulate? One person said the galvanized post is conductive but then said theres a nonconductive coating over the galvanization. Hmmmm.

7. Today I installed an automotive signal amplifier. At first I thought I detected a slight difference in the reception but then when I disconnected the amplifier there was no difference.

8.If a signal is getting to my outdoor antenna, is it nessessarily possible to get the signal to the radio or can there be circumstances which may make this impossible?

9.I'm used to working with electricity. If you touch a wire to a fairly clean metal ground you usually have a ground. Is the ground needed for radio signals different and much more critical so that anything less than a perfect ground will result in little or no signal?

10.I tried using a long wire antenna also but the result was identical to the automotive antenna I am currently using.

11. I haven't given up on the idea of building a loop antenna or adding some kind of circuitry but for now I want to try to keep it simple until I learn more.

Thanks again.

Sofasurfer

It is difficult for me to believe that you installed (properly) an
amplified AM antenna from a modern car, on the outside of the metal
building, and didnt get decent reception.
Do you have some reason to *not* use the radio from a "broken car"?
Car radios are designed to work in the environment you have inside the
metal building at work.

You must already be aware that the problem you are encountering is the
result of the AM radio waves being unable to exist within a metal cage. It
is necessary to acquire the radio signal on the *outside* of that metal
box/building.
An amplifier *at the antenna* is required to then send the signal to the
radio.

No, I'm just trying to get back to the original discussion which
was: Do SWR meters need 50 ohm coax surrounding them to establish
the assumed 50 ohm environment? The majority of SWR meters have
no Thruline and MFJ seems to make no attempt to establish a 50
ohm environment like Bird does. What is the Z0 of a meandering wire
surrounded by an aluminum box?

The original discussion (V/I ratio is forced to Z0) had nothing to
do with Bird wattmeters. The original discussion was about SWR meters
in general (which the Bird is not). The mythbusters thing was an
interesting diversion away from the original question which remains
unanswered.

It's a guess as to whether you are going to correct
your errors about thin-film coatings before you
expire. What is it about the following that you don't
understand?

www.mellesgriot.com/products/optics/oc_2_1.htm

"Thin-Film Interference"

"Thin-film coatings also rely on the principles of interference. Thin
films are dielectric or metallic materials whose thickness is comparable
to, or less than, the wavelength of light."

Speaking of 1/4WL thin-film coatings:

"Clearly, if the wavelength of the incident light and the thickness
of the film are such that a phase difference exists between reflections
of p, then reflected wavefronts interfere destructively, and overall
reflected intensity is a minimum. If the two reflections are of equal
amplitude, then this amplitude (and hence intensity) minimum will be
zero."

"Amplitude minimum equal zero" means all reflections have been eliminated.

- or even more vague - an assumed 50-ohm environment?

Or an evironment of any other impedance.

An engineering definition please! In plain English.

Then perhaps I can understand what you are all waffling about.

Thank you.

Reg, G4FGQ.

Something has changed in the vicinity. Has anybody parked a great
metal-clad vehicle near to your home? Or shifted anything else which
could behave as a reflector of radio waves.

Or has the room furniture, including the TV set, been changed around
recently?

Try changing the TV set. What happens?

Reg.

an interesting diversion until everyone was convinced that you were off the wall. now its time to re-open a dead thread???.

as far as cheap swr meters, the daiwa, swan, and mfj manuals all require 50 ohm coax 'for accurate readings'... a joke by any standard of measurement for that type of instrument. but just to put this one to rest quickly... i set up my tdr and ran some quick measurements. this tdr will resolve a 6" 75 ohm jumper in the 25' or so of 50 ohm test cable that i used. i measured an mfj-815b and a daiwa ns-660pa and they are indistiguishable from the 50 ohm line. so the answer is yes, they do internally look like a 50 ohm line section.

Hi OM,

It does make sense, what you are describing in the place of sense is
frustration.

That you got a boomin' signal proves that it exists on the antenna,
where the antenna is. It also proves your method of attachment, or
the radio is FUBAR. If this happened with two good, known working
radios, it then proves the problem is with your attachment.

All of this is clear beyond one second.

Most radios that offer the option of external/internal antennas also
demand a switch be thrown to actually make the change. This switch
may not be the best of devices - and that is your best hope, that or
you are inadvertently shorting the input (this goes back to the
evidence pointing at your skill in attaching the antenna).

Sounds like it is time to call in another set of eyes looking over
your shoulder. Diagnosis over the Web has its limits in achieving a
solution to a hardware problem at the most fundamental level. Whoever
is looking needn't be an expert, or even anything more than sentient.
They need only ask the right question at the right time:
"Howcum do it you like that?"
To which you respond:
"Damn, I meant to...."
and the radio begins to play. History is full of such epiphanies.

Reg Edwards wrote:
> - or even more vague - an assumed 50-ohm environment?
> Or an evironment of any other impedance.

The transmission line reflection model tells us that the Z0
of a transmission lines forces the following relationship.

Vfor/Ifor = Vref/Iref = Z0

A "50 ohm environment" used in the context of the previous
discussion would be one in which the above relationship
is forced on the system at certain points in the system.

600 ohm transmission line going from a tuner/balun to an
antenna establishes a 600 ohm environment for the signals
on the transmission line. An SWR meter calibrated for 600
ohms will indicate the actual SWR.

About a year ago, based on a discussion that you and I were
having, I asked the sci.physics.electromag newsgroup how
long a piece of RG-213 coax has to be to establish the
above relationship. The answer was that the non-TEM product
terms decrease at about 1/e every two inches for RG-213.

The RG-400 coax leads going to and from my SWR meter are
two feet each. So I asserted to you that my SWR meter
was reading the actual SWR in the middle of that run of
RG-400. I think you disagreed with my assertion but I
cannot remember for sure.

ah, good cecil hasn't replied yet... sorry, i should have put this in the same message, but the sun was trying to come out and i had to take advantage of it. we haven't seen the sun here for the last 10 days which is the only reason i was bored enough to bother getting into one of these 'discussions' again.

now for the other part of the story. cecil states that a 50 ohm 'environment' must be established around these meters to get proper readings. this 'environment' requires some unknown length of 50 ohm cable on both sides of the meter. i can disprove this one easily... i again used the two meters above. first, attach 50 ohm dummy load to the meter, set transmitter to 100w forward on the meter, read reverse... there is always some small movement, but not much more than a needle width on either one. now, get 1/2 wave of 75 ohm cable, attach between the dummy load and the meter antenna output... again adjust for 100w forward and voila, same needle wiggle as before. what does this mean? well, if indeed the meter was relying on the length of 50 ohm coax on the output to 'establish the environment' as cecil seems to think is necessary then the 75 ohm cable should have upset this 'environment' and caused an incorrect reading... since the reading was correct for a 50 ohm meter then it must be that the required length of 50 ohm cable is zero.

now of course cecil will rant and rave and say the meter is reading incorrectly since there is obviously some reflected power in the 75 ohm cable. and he will be correct on that point, however, once you change the reference Zo to 50 ohms inside the meter there is no reflected power to measure since the load presented at the end of the 75 ohm line is 50 ohms. QED.

Try it with 75 ohm coax. I suspect they will be equally indistinguishable
from 75 ohm line.

Actually, the question logically follows from the reflection model.
Under what boundary conditions does a piece of transmission line
force Vfor/Ifor = Vref/Iref = Z0 to a specified accuracy?

The question remains: Does the MFJ's physical design ensure the
physical reference Z0 is 50 ohms or would it perform just as
well in a 75 ohm enviornment simply by recalibrating it for
75 ohms?

In other words, it is sampling a voltage and current completely
divorced from any *physical* reference Z0. The actual reference
depends upon an arbitrary setting of a calibration cap which
has no effect at all on the *physical* reference Z0.

If it had an effect, the Z would change, wouldn't it? The cap has a
Z, that much is sure. The purpose of the cap is not what you ascribe
to it - but that is par for the course as this inclusion quoted above
has no meaning either in or out of context.

then look up article 3.19 in 'fields and waves in communications electronics' which is where they derive the fringe effects for a step change in spacing between two plates. this is where they refer you for calculating the effects of evanescent modes from a more complex problem stating that the results are identical with the static case in 3.19... in the derivation of the complex case of a step change in a cable they show that a single lumped capacitance added at the step is an adequate representation of the discontinuity when calculating the evanescent modes below cutoff. in 3.19 if you disregard the fields along the length of the step it ends up in an equation: Z=h/pi(exp(pi*W/V0)-1-pi*W/V0_j*pi) the important part is obvioulsy the decay factor in the exponential which goes as exp(-x/h) where h is the separation in the planes... or you get one 1/e reduction for each distance equal to the spacing which in rg-58 or rg-8x that i used is something like 1mm or less.. so how far down do you want to be? in 4.5mm you are down to 1% which is well under the accuracy of these cheap meters, and much less than the length of even the connectors on the meters.

CRB-

Years ago sensitivity might have been measured using a "20 dB quieting" method. You would inject an unmodulated carrier and increase its level until the noise output of the receiver decreased to one tenth of the no-signal value. This might work for tuning to improve that one receiver's sensitivity, but it isn't the greatest for comparing different receivers with different bandwidths.

Isn't SINAD an acronym for "Signal In the presence of Noise And Distortion"? I don't fully understand how it works, but assume there is a 1 KHz filter feeding one channel that is compared to an un-filtered channel.

What I want to know is how to build one. Does anyone know of any SINAD construction articles?

Here's a schematic of an MFJ SWR meter at the bottom:

http://www.mfjenterprises.com/man/pdf/MFJ-816.pdf

What do you think is the purpose of the 10pf variable cap
if not to vary the voltage in the voltage divider?

The question is: Between the "transmitter" terminal and
the "antenna" terminal, what determines the physical
characteristic impedance of the sampling circuit?

I always see a few that delight in attacking MFJ. Find me another company
that produces products for a reasonable price for the Ham.

Do they get any props at all, hell no. Some idiot pisses and moans that the
MFJ $19.95 what ever is less accurate than their favorite $350.00 supplier.

Why would you not "trust" an MFJ to measure anything?

If you can't give a specific reason to avoid an MFJ product, then what is
gained by your supercilious remark.

Not just the radio. Check the TV F connectors. It is easy to lose a ground there. The kind that push on, instead of screwing on to the set are especially bad. Try pushing the coax into the F connector while the TVI is present. If you have 300 Ohm twin lead, see if one side came loose. You didn't add a preamp, right?

Hello Fred,

If you have a calibrated RF signal generator that provides 1 kHz
modulation and an rms voltmeter that covers communication audio
frequencies (say to 3 kHz), then the only thing you need to make SINAD
measurements is a 1 kHz notch filter. You can find schematics for that
in the ARRL handbook and elsewhere.

Good luck!

Maybe you can help. I have an MFJ-259B antenna analyzer and a
dual-trace 100 MHz o'scope. Let's say I have an unmarked 2 inch
piece of coax and I don't know the characteristic impedance.

Using the MFJ-259B and o'scope, how could I ascertain the Z0 of
that 2 inch piece of coax? This is similar to the problem of
determining the physical Z0 of a poorly designed SWR meter.

You don't know, do you? :-)
It adjusts the frequency correction at the high end of the meter's frequency range. Too bad this version of the manual doesn't lay it out for Xeroxing - many of their other manuals do. This is a commonplace of the Bruene design.

>The question is: Between the "transmitter" terminal and

You don't know that one either, do you?

The turns ratio and the 82 Ohm load resistor IS the Z of sampling circuit; the capacitor provides the e phase reference and tracking across frequency. It is very lightly loading as a series load by design and as evidenced by Dave's measurements.

Odd that you couldn't have said this yourself - rather ordinary stuff.

> Any reason I shouldn't use a choke balun out of my tuner to feed
ladderline
> up to a dipole?

==========

There's no reason whatsoever. In fact it is the obvious thing to do.

The choke allows you to connect an unbalanced tuner to any balanced feedline via the choke.

A balanced tuner is entirely unnecessary in almost all circumstances.

The choke is simply a pair of wires wound together around a ferrite toroid. Or it is a coaxial pair wound round a toroid (which for various reasons is slightly less efficient and is physically less convenient.) So the pair of parallel wires is the better form of construction.

The choke behaves as a short length of transmission line of the same length as the pair of wires wound on the choke. Which is very short when a ferrite toroid is used.

Because the length of line is an impedance transformer it transforms the input impedance of the transmission line to somewhat different values especially at the higher frequencies. At the lower frequencies it may just as well not be there.

Which means that the tuner L and C settings are different to those which occur when the choke is not there. But often, when the choke is in use, the tuner finds it easier to match the line and antenna to the transmitter. Which is the sole purpose of the tuner.

The number of turns wound on the choke must provide an inductance and a reactance of about 4 or 5 times the load resistance required by the transmitter, usually 50 ohms, at the lowest frequency of operation. This depends on the permeability of the ferrite core material.

At the higher frequencies it is best that the length of line wound on the torroid should not exceed 1/8th of a wavelength at the free-space velocity. This is usually not too difficult to manage.

To simplify, get a 2" outside diameter ferrite ring, of HF grade marerial, wind on 14 or 18 turns, and get on with it.

A choke balun is the most simple of radio components to construct, yet its behaviour is amongst the most complicated of components to analyse.

Dave, I note the work above estimating the rate of decay of the effect
of the discontinuity, and we have seen another analysis of the decay
rate (mis)quoted.

Doesn't the impact of the discontinuity at a distance x depend on the
magnitude of the products of the discontinuity times the attenuation
at distance X.

These discussions do not seem to have attempted to estimate the
magnitude of the products of the discontinuity.

Think about all the places where we do not preserve nominal Zo, and
whether significant power is diverted to other than the dominant mode
and subsequently lost. Look inside a HF transceiver, it is full of
discontinuities between the PA collector and the coax socket. Design
practice for HF transceivers does not consider potential losses from

evanescent modes.

If there were significant dissapative losses from such
discontinuities, don't all the texts on stub tuner design need to be
rewritten.

Where is the experimental evidence that significant power is diverted
in practical circuits and transmission line discontinuities?

My experiment reported at the beginning of the thread could be varied
to include another Bird at the dummy load, and to compare the power
loss between Birds with the expected cable loss (in the dominant mode)
to indicate whether there was another dissapative loss mechanism at
work.

I won't waste the time on the experiment because I anticipate that
instrument errors and cable specification errors would swamp any
likely effect of the discontinuities. IMHO, a well designed experiment
would require more accurate measurement of the dominant mode loss of
the 75 ohm cable, and more precise and accurate power measurement
equipment.

To demonstrate that point, I have just performed a test at 10.1MHz
with the Bird 43 and the 5.27m of 9275 on the load side with o/c load.

The measured return loss was -0.36dB. (Always seems un-natural
specifying a loss as -dB). I estimate the return loss should have been
-0.25dB (using the calculator at http://www.vk1od.net/tl/tllce.php),
leaving an unaccounted for -0.11dB. The differences are smaller than
the tolerances / accuracy of the equipment.

Perhaps it does demonstrate that the loss caused by the discontinuity
is not significant in terms of the specified accuracy of the Bird 43.

the equation gives the potential and flux functions, so its the
voltage/current essentially. no body calculates power functions unless they
are doing something strange.

who is kevin rhodes? what reference books is he cited in as calculating
that and using what method? and that seems like an awfully long distance
for a fringe effect from a change in diameter of the conductors... but that
is just a gut feeling based on my understanding of the field equations.

yes, this is true also. the initial amplitude of the evanescent modes is
proportional to the size of the discontinuity. when going from 50 to 75
ohms that is a relatively small discontinuity to start with and the modes
decay exponentially from that starting point. there are probably bigger
losses due to interconnections between components and the connectors on the

case than are caused by the actual change in cable impedance.

Cecil,

Go back and read your own post:
GaR1f.9892$oO2.4025@newssvr27.news.prodigy.net

You quoted Kevin Rhodes:

>(1/45m)**2 = (1/.203")**2 + kz**2
>Clearly, kz must be imaginary to make this work. thus an
>evanescant, non-propagating wave:
>kz**2 = (1/45m)**2 - (1/.203")**2
>To the accuracy used to date, the first term on the right
>is negligible, so the decay rate, alpha, can be estimated:
>alpha**2 = - (kz)**2 = (1/2.03")**2

How does rearranging the terms here increase 0.203" to 2.03"?

In any event 0.203" is an overestimate of the spacing, 0.203" is
actually half the overall diameter of RG213.

I don't really understand this mathematics, do you understand the
thing you are citing?

Hi Owen,

Some of the minor points here would be, to use the term you use yourself later in your post, swamped. The swamping contributors are generally attended to in design, and those corrections draw in and encompass these smaller points.

A lot of this is handled by the low pass filtering following the final stage's Z transformer in a transistor set.

>If there were significant dissapative losses from such
>discontinuities, don't all the texts on stub tuner design need to be
>rewritten.

These would be called mismatch loss, which is not dissipative, but rather what power was not delivered, that could have been if not in the face of the discontinuity. Think of it as a loss of opportunity, not a loss down the drain. Consider that same low pass filter following the transformer. It withholds the power found in the harmonics, and yet few filters need as much cooling as do the finals transistors that are arcin' and sparkin' with those transients.

The low pass filter is a cheap alternative to linearizing the finals stage and thus reducing those spurs. This would run the finals at a lower gain however (to be put into what Bode calls the noise gain, or negative feedback), and you would need more dollar investment for the same power out.

>Where is the experimental evidence that significant power is diverted
>in practical circuits and transmission line discontinuities?

A practical example can be found in any RADAR system. You have ATR tubes that perform power steering in waveguides. The list goes on with lots of goodies (can anyone explain the Magic-T?) as RADAR is particularly theatrical in this arena.

Every connection to a waveguide uses the physics of discontinuity to suppress leakage. Examine the choke fittings, they are series shorted tuned cavities used to bridge joints that necessarily have some prospect of not maintaining entirely mating interfaces.

>Perhaps it does demonstrate that the loss caused by the discontinuity
>is not significant in terms of the specified accuracy of the Bird 43.

And then there is that distinct possibility. In such cases you design
the test to discard that perturbation by increasing the effect being
investigated. This is why I suggested a large mismatch would render
this chatter about 4W as being inconsequential.

Yes, I should have qualified the statement to scope it at HF. I am
aware of the risk of excitation of undesirable modes in waveguide and
the need for mode traps to deal with them where their propagation is
undesirable.

I am not questioning whether physical discontinuities give rise to
electrical changes that can be explained or modelled with by lumped
constants or excitation of other propagation modes, I am questioning
whether the effects are significant in practical applications below
microwave frequencies, and especially at HF.

From page 27-8 ARRL Antenna Book 15th edition. "Capacitive voltage dividers, C1-C3 and C2-C4, are connected across the line to obtain equal-amplitude voltages in phase with the line voltage, the division ratio being adjusted so that these voltages match the voltage drops across R1 and R2 in amplitude."

In other words, it is the main Z0 calibration setting that sets the sampled voltage equal to the sampled current while driving a dummy load equal to Z0. Frequency response is a completely secondary consideration.

If the range of C1 and C2 are great enough, the wattmeter could be calibrated for 75 ohms rather than 50 ohms.

Exactly how much effect does that light loading have on the primary voltage/current amplitude and phase? Enough to be detectable if the V/I ratio is not 50 ohms?

The guy from sci.physics.electromag whom I quoted previously in the "V/I forced to Z0" thread. It appears that he accidentally replaced the conductor spacing of 0.203" with 2.03" in his calculations. If that is corrected, his values tend to agree with yours given the different conductor spacing between RG8X and RG213.

So can we say, the lowest order undesired mode should reduce intensity by a factor of 1/e in about one conductor spacing, 1/e^2 in two conductor spacings, etc.?

ugh! all of this was over a slipped decimal point??? so we are down to .2"
transition, which pretty much agrees with the one i came up with, and which
basically means that by the time you are out of the connector shell you are
back at Z0. and since the meter takes its own 50 ohm 'environment' with it
for sampling it is reading every thing exactly as it should... and exactly
as has been measured... and there is no requirement for some particular
length of 50 ohm coax on either side of a meter... what a waste of a
perfectly good argument, you better apologize big time for this one cecil!

There is NO R1 and/or R2

This is familiar bait and switch methods so common to your trolling.
Changing the schematics to suit the argument can make any answer come
alive.

Like I said, if you were already familiar with this, you would have
said so and skipped all this stageshowing.

>In other words, it is the main Z0 calibration setting

An interpretation spanning as many documents as it takes to assemble
all the words xeroxed to this posting.

>If the range of C1 and C2 are great enough, the wattmeter
>could be calibrated for 75 ohms rather than 50 ohms.

Notably, there are no C1 and/or C2. Even more, if there were, any
competent tech in this group would be aware that it also would take a
similar shift in value of your R1 and/or R2. In fact, this
overstatement by calling out BOTH Cs needing change begs the chuckle
reflex being stifled.

>>>The question is: Between the "transmitter" terminal and

>to be detectable if the V/I ratio is not 50 ohms?

[clue: this is in the portion of my original post that you omitted.]

I would normally ask my students "What do you think?" but there is a
danger of that here, with so little obtained in return for so much
said.

Rather, I will offer "Think about it. How much power does it take to
swing a 1mA meter even full scale when there is a 500KOhm calibration
resistor (imagine that, do we assign THAT as the Z?) limiting it."

Something about Iï¿½R comes to mind for max power (300W) which works out to half a watt out of 300 supplied. A simple, back-of-the-napkin computation suggests less than 1%. A similar study of the actual load of 82 Ohms needs only be cast back through the Nï¿½ turns ratio. Seeing that it, too, is probably a quarter Watt resistor that we are still talking about less than 1% consumption.

So, anyway you slice and dice it without actually counting the turns ratio, the tech at the bench would easily offer the meter injects only half an ohm or less series resistance into the line.

I won't deny it!

Now, if you want my honest assessment, I find the whole thing fraught with ethical questions.

What if someone isn't listening to the radio when the message is broadcast? What about the people who don't live near railroad tracks?

If this thing is to *actually* work, it would have to be space based. Work with a database of the frequencies in use in the affected areas. broadcast on them as the need arises. FM will be easy. AM will be some more work. Of course you'll still have to deal with the people who aren't listening at the moment!

Of course if it just a research project to burn up some money, then *that* is a different subject altogether!

I do apologize for the slip of the decimal point and for not finding it
before today but I think you guys completely missed the context of the
original argument and instead went off on several interesting tangents.

Now back to the original context: As Reg pointed out, you can't have an
SWR on a feedline that doesn't exist so how much 50 ohm feedline must
exist *external to the SWR meter* to be able to report a valid 50 ohm SWR
reading *on that coax*? Turns out to be around an inch, more or less, and
that is a good thing to know. Thanks for answering the question even if
in a time consuming way. If you had simply said that 0.2" of 50 ohm
coax is required to establish a 50 ohm environment *external to the SWR
meter*, we could have started arguing from that point and it would have
saved a lot of time and effort.

What is the validity of context when it is buried in error? This is
this is the pollution of argument that discards proper method and
accuracy to prove absolutist principles.

The point you miss is that when the errors are corrected, they
invalidate your premise - context is quite obviously out the window at
that point.

Why the belated revelation of the Bird 43 coupler Zo? In a post on 9 Oct on the earlier thread I stated:

"My suggestion is that the sampler inside a Bird 43 coupler section is sufficiently far inside the 50 ohm coupler line to provide measurements within the instrument's stated accuracy of what is happening within the 50 ohm coupler, irrespective of whether, for instance, a 75 ohm line is attached to the coupler on the load side."

You must have read it, you responded to it with your message e2W1f.5490$Zs3.3003@newssvr25.news.prodigy.net .

Perhaps the honest way to deal with the situation is to acknowledge that your statement quoted at the top of this post was just not true, rather than to edit the words to shift the context to somewhere else where it might be true.

It would be gracious of you to return to the myth, read it carefully and think about it, and to respond restricting yourself to the myth as stated, without qualification or obfuscation, is it a myth YES or NO.

To save you the hassle of finding it, here is:

The myth: Measurements with a Bird 43 of the conditions on the Thruline section are invalid unless it has some minimum length of 50 ohm line on both sides of itself.

Myth or not, YES or NO?

Owen

Have played with that type of Bird. Worked well as I recall. Have also
made a Bruene type - fairly constant readings over wide frequency range.
Yes 40m is a bit ordinary at the mo for short distance.
Cheers,
Alan

OK, Cec, I have a better idea of what you mean by '50-ohm
environment'.

You refer to: -

Vfor/Ifor = Vref/Iref = Z0

with which I agree.

But Zo is a pure resistance and the relationship can be true only when
there is no phase shift between Vfor/Ifor and Vref/Iref.

Which means, in the ideal meter, the voltage tap-off and current
tap-off points must be identically located within the instrument.

I would now like to go off in a slightly different tack to these
extensive threads.

There is a length of conductor between the input and output terminals
of the meter. It cannot be avoided. For obvious reasons related to the
high-frequency response and accuracy, the Zo environment along this
conductor has to be maintained as good as is reasonably possible. (
With the common or garden SWR meter nobody bothers very much. It
hardly matters anyway.)

The location of the voltage and current tapping points along the
conductor doesn't matter two hoots. What matters is the distance
beween them because of the phase difference. Small errors due to
misplacement are unavoidable and have to be lived with.

Getting to the point of this message: - The length of transmission
line inside the meter and the unknowns regarding 'Zo environment' play
no part either in operation or analysis of the meter.

The story that the length of line inside the meter is used to detect
and measure standing wave ratios is just another old-wives' tale which
confuses CB-ers, novices and professional engineers alike.

(By the way, if there is a short transmission line of any sort inside
the instrument, its length can be used to set the measuring
sensitivity. The longer the line the greater the sensitivity. But the
longer the line the greater the measuring errors and the worse the
frequency response.)

Reg, G4FGQ.

The old Canadian Department of Communications Document RSS 125 Issue 1,
Released August 1st, 1976, precisely describes the method of SINAD
measurements for SSB equipment. In the past 25 years or so, HP's distortion
analyzers (such as the HP8903B) were used for this measurement. In the late
60s and early 70s I have seen Heathkit distortion analyzers used for SINAD
measurements. The latest versions of RSS125 seem to be more in line with
FCC standards, where receiver specifications are not required for
certification purposes (See
http://www.agiletestgroup.com/ICCertifications.html).

I've been reading this thread while biting my tongue concerning the Zo of the SWR measuring device. IMO the basis for the Zo of the device is being overlooked, although Cecil is coming the closest to describing it.

We are discussing the Bruene version of the device in which the inductance derives a sample of the current and C1 derives a sample of the voltage. When C1 is adjusted to obtain the correct voltage for the voltage-current ratio to equal Zo at that point, such as 50 ohms, the device provides the correct readings when the line impedance on the load side is Zo. The line impedance Zo on the input side is irrelevant.

If C1 is adjusted to obtain the correct voltage for the voltage-current ratio to equal Zo of 75 ohms it will provide the correct reading when the line impedance Zo on the load side is 75 ohms.

The line impedance of either the input or load transmission line is irrelevant to the basis for the Zo of the device, therefore a length of line is unnecessary to establish a Zo environment, the current sample and voltage sample establish it..

One can terminate the device with a lumped impedance and get the same answer as with a transmssion line whose input impedance is the same as the lumped impedance.

Walt, there's one thing I don't understand about what Dave reported.
As I understand it, these were the test setups.

TDR---50 ohm coax---MFJ---50 ohm coax---50 ohm load

The TDR doesn't see the MFJ wattmeter.

TDR---75 ohm coax---MFJ---75 ohm coax---75 ohm load

The TDR sees the MFJ wattmeter.

If the MFJ in the second setup were recalibrated for 75 ohms,
would the TDR not see it?

****

The threads for the past few days have all diverged from the
original question which was:

How long must the 50 ohm coax connected to the SWR meter be
for the SWR meter to report a valid SWR on that coax? The
answer obviously cannot be zero length.

In my MFJ, the toroid and calibration cap are about 1/2" apart.

> The story that the length of line inside the meter is used to detect
> and measure standing wave ratios is just another old-wives' tale which
> confuses CB-ers, novices and professional engineers alike.

And if you will remember, the original question didn't involve the
SWR meter at all. The question was: Are my 2-foot sections of RG-400
connected to my SWR meter long enough to ensure that the SWR meter
reading is valid for the coax? Remember that argument?

The threads for the past few days have all diverged from that
original question which was:

How long must the 50 ohm coax connected to the SWR meter be
for the SWR meter to report a valid SWR *on that coax*? The
answer obviously cannot be zero length.

yeah, in your dreams your hardline as 6" in diameter! its probably not even
6" long!

by the time you put enough adapters on it to get it down to your so-239 or n
connector on your cheap swr meter it will be.

>The TDR sees the MFJ wattmeter.

It seems to me the amount of the discontinuity the wattmeter calibrated to 50
ohms the TDR sees would be determined by the tightness of coupling of the
sampling inductance and capacitance to the main line.

Cecil, as I explained earlier, if we're considering the Bruene type SWR
indicator, the setting of the sampling cap in relation to the inductive sampling
determines the measurement reference, not the length or Zo of the coax. So I
repeat, with this SWR indicator zero coax length is sufficient. It will produce
the same answer with a lumped impedance as the load as it will with the same
impedance appearing as the input impedance of a coax.

Hi Walt,

You might force what appears to be SWR meter action, but what you
describe above is not sufficient to offer the original accuracy; and
at that point why bother putting a screwdriver in and twisting things?
To accomplish the purpose being discussed takes TWO changes (of the
THREE variables of design) as I have already discussed.

Except under the most fortuitous of circumstances, there is nothing
inside the meter that even closely approaches Z0 - or has to.

As an aside to your comments and directed to the novitiates, any
number of Bruene variants can be found where those variants offer less
than optimal performance. However, quality equipment offers that the
line transiting between input and output connectors and thru the
sensing core IS Z0. This consideration takes so little effort, that
those designs that do not are probably suffering other short-cuts away
from intelligence. This opprobrium goes equally for arguments that
presume there is no line either.

Richard, I grew up listenting to those stations. WJR was originally on 750, but went up one slot after the NARBA agreement in the early 1940's. Incidentally, WJR was originally WCX, transmitter at Pontiac, which I listened to beginning in 1925, but changed to WJR in 1929 when it was purhased by the Jewett Radio Corp.

I grew up in Mt. Pleasant, 115 mi NW airline from Detroit. Even with 500 W WBCM on 1440 40 miles away in Bay City, we had no primary BC service, which is what prompted me to build a local station after returning home after WW2. I engineered and built WCEN, 500 W 1150 in 1948, and on the air in 1949.

Mt. Pleasant is in almost the exact center of lower MI, it is the home of CMU, Central Michigan University. I considered both WMTP and WCEN for the call sign, but decided on WCEN. However, when I applied for it, FCC said it was already assigned to a Coast Guard vessel. After some research I discovered that vessel had been decommissio;n 10 years earlier, so I contacted Treasury and asked them the release the call back to the FCC for reassignment to me. They did and the FCC did. Sadly, the station was sold in 2004 to a Saginaw based outfit, retaining the FM outlet, but deleting the AM.

But Walt, there no SWR possible on a zero length line. I think it
was Reg who said that first. I can now see how the initial confusion
arose and why the thread drifted.

Source---75 ohm line---SWR meter---load

The SWR meter will not report the actual SWR on the external 75 ohm line.

Source--75 ohm line--50 ohm line--SWR meter--load

The SWR meter will report the actual SWR on the external 50 ohm coax if
the external 50 ohm coax is _______ long.

Turns out the answer is a lot smaller than I previously thought.
The answer is less than one inch for the most popular 50 ohm coax's.

I didn't mean for the original question to be a trick question but it
apparently turned out that way.

Let us be clear: Richard Clark is not in the neighborhood of Flint.

A few factories still exist in the Flint neighborhood that are likely
significantly to attenuate AM broadcast signals (due to the plant's
construction). Square miles of such factories have been leveled to bare
ground in the I75 corridor.

One must conclude that the programming of local AM broadcasting stations
is not desired by the person having difficulty. Almost all of the local (to
Flint) stations are strong enough where the plants are located to be heard
inside of a plant.

A scheme that could be used to listen to WJR or WWJ is to have the audio
of an AM receiver in a vehicle located in an adjacent parking lot modulate a
small FM transmitter. A conventional FM receiver inside of the plant is
likely to receive a suitable signal. The power required by the system in
the vehicle could be small.

Source record: 68659

Currently I have a coax fed trapped 75/40M dipole up between two trees. The spacing of the trees (a bit over 110 feet) allows this antenna with no extra length allowed, except for minimal support line and insulator length.

I plan on replacing this dipole with 450 ohm ladder line feed doublet so I can operate on more than just 75/40M, however a full 1/4 wave length for 75 would be too long to fit between these trees.

My QUESTION(s): How effective would a balanced fed dipole of about 100 feet length be on 75M ? Should it tune OK with a tuner such as the new MFJ balanced tuner? Or, if I were to put either the old 40M traps, or wind coils for the new dipole to shorten 75M resonance, would it then tune OK on all bands from 75M down with balanced feed?

Thanks for the info, Frank.

Actually, the RSS125 on the site doesn't contain the procedure, but
RSS181, also available at that site, does.

FWIW, the procedure is basically what has been discussed, except that
the signal generator output to be recorded as the receiver's sensitivity
is that level which produces a 12 dB SINAD at 50% of rated audio output!
Probably a more realistic test than allowing the AF stage to operate at
a low-distortion level of something like 1% of rated output.

Hi Ed,

The answers to your questions are found in the quote above.

If those bands on the old antenna were already resonant, and they
matched, then you didn't need 450 Ohm ladder line.

If you are going to use 450 Ohm ladder line on a generic doublet, it
stands to reason you won't be resonant much anywhere (or you don't
count on it) and you anticipate tuning and use this line for low loss.

The only thing left to be said is about the lobe structure at any
particular frequency. Long, long antennas at high frequency develop
sharp lobes and nulls. That being said, it is more a matter of where
you are pointed and where you want to be heard. The solution to that
is to use a fan tail design for the higher bands' sake.

Using a doublet, ladder line, and a tuner is classic - it works fine.

Space-based wouldn't work. You can't get a spot footprint small enough on
the earth's surface to make this do-able. Iridium comes about the closest,
but would you put up a constellation to provide the footprints and not use
it 99.999999999% of the time? :-)

Cheers.

Ken

Cecil, this is the opposite to your stated YES opinion just three
hours ago.

I am beginning to form the view that your opinion is just the opposite
of that expressed in the last posting you read, that you will argue
for arguments sake. When I look for consistency in you postings, it is
that they are consistently arguments against other propositions, even
if it means you have to change your own position to remain opposed. To
be kind, the devil's advocate.

If you are not satisified with the antenna you have then I would put up about 130 feet of wire and feed it in the middle with the balanced feed. If you can not get up the full 130 feet or so of wire, put it all up and let the ends hang down. That is the support ropes could be attached 10 to 15 feet from each end and then you let whatever is left over hang down. Just don't let the ends reach close enough to the ground where someone could reach them. Shock and RF burns.

If you go to the 100 feet and feed it with open wire , you are trying to make the antenna into a g5rv if you use whatever length of feedline the g5rv calls for. Not really that good of an antenna for working all bands.

Make it 102 ft. and you will have the G5RV length about which
virtually everything in the world is known. It works so well
on 75m that you should not be able to notice the difference.
How easy/hard it is to match will depend upon the feedline
length.

Jerry Martes wrote:
"It is difficult for me to believe that you installed (properly) an amplified AM antenna from a modern car, on te outside of the metal building, and didn`t get decent reception."

The usual AM car antenna has an impedance of about 5000 ohms. Car coax is special. It has a fine-wire center conductor inside an air-dielectric covered by metal braid. It marches the 5000-ohm antenna.

50-ohm coax makes a capacitive voltage divider (uigh-value attenuator) when used with a car antenna. The longer the 50-ohm coax, the more severe the attenuation.

The active (amplified) antenna could easily be designed for a high input impedance and a low output impedance. It coulf use a an emitter follower as an output stage. What Sofasurfer has is unknown.

A low-impedance shielded line is less susceptible to noise pickup than unshielded wire. Coax is OK. Balanced twisted pair is not too susceptible to noise. But as Sofasurfer`s experience shows, severe mismatch is a killer. He needs either a low-impedance antenna or a matching device to step the high-impedance antenna output down to the line`s impedance. A hollower can do that almost without losing voltage. A broadcast loop for the AM band is a low-impedance because the wavelengrh is so long or it can be tapped or loop-coupled to a low impedance.

Best regards, Richard Harrison, KB5WZI

Ed,

When you analyse the performance of a centre fed dipole antenna system, you will find that for most practical dipoles, the challenge is getting most of the power to the feed point, rather than the ohmic losses in the radiator itself.

By the time the dipole is long enough to obtain acceptable performance from a practical feed system, the loss in the radiator itself is typically less than 0.5dB (unless you contrive do something pretty silly).

It turns out that it becomes quite challenging to implement an efficient feed system (especially over a wide frequency range) where the dipole is less than about 35% of a wavelength at the lowest frequency.

Now, the 100' you nominate is so close to the length of a G5RV that you could draw some information from analyes of the G5RV. I wrote one that focusses on the performance of common distortions of G5RV's design and examines particularly the feed system performance, which I suggest to you is the most significant influence on antenna system efficiency in this case. Unlike many other analyses of the G5RV, this does not just consider ham band performance, it models performance every 100KHz from 1MHz to 30MHz, so you can see a continuous view of the behaviour. The article is at http://www.vk1od.net/G5RV/ .

But you weren't asking about a G5RV were you. Look at Figure 10 and the "Classic tune feeder" topic which is a 30m dipole fed with 23m of ideal 600 ohm open wire feeder. (Ladder line won't perform quite that well, especially when wet). That topic is directly relevant to your proposal.

Nothing in the feed system affects the pattern (in three dimensions), that is determined by the length of the dipole, and its environment.

Hi Richard

I had assumed that the OP was just interested in just getting an AM radio
to work inside the metal building. And, actually I'm no expert on the
design of AM receivers. I have considered the "car AM antenna" to be more
of a probe of the currents conducted on the outside of the car. I thought
the reason that the "high impedance coax" to be used for car AM radios was
because that high impedance is more importantly the lowest shunt capacity.
I've been considering the car's feed line to be a capacitor shunting the AM
signal across the receiver's input, and across the antenna connection.

There are many cars today that have amplifiers mounted in the base of
their AM antennas. Those "amplified antennas", like in even VWs will work
OK even with a lower impedance coax to the receiver.

The antenna doesnt need to be on the top of the building. It only needs to be outside, as you know.
The cost of the entire radio and antenna amplifier from a wrecked VW is probably affordable in Detroit.
I have aQST article that deal with this "amplified AM antennas" subject.
I thought it was best to wait for sofasurfer's response before my writing alot about the theory and/or details.

Jerry

Hi Johan, I think you have the right idea. A broadband power
limited small antenna suggests resistive loading at the feedpoint. It
will work, just not very well until you get above the frequency at
which the wire portion starts having some efficiency. As a guess, this
one might do OK above 14 MHZ.
A magnetic loop generally refers to a small loop with a very narrow
bandwith, tuned by a variable capacitor. The claim that this is a
magnetic loop on low bands does not hold up because of the broad band
claim.

Hi,

Please, somebody explain the following to me:

/ What will be the next great invention on the order of the laser? We
don't know, but clever new ideas keep coming along. The
second-place award in the technological innovation competition went
to Marin Soljacic (MIT) for his concept of wireless, non-radiative
energy transmission. Just as in the quantum case in which the
Schrodinger equation allows for a wave trapped in a box to tunnel
out, so Maxwell's equations allow for the leakage of electromagnetic
energy from an electromagnetic resonance object. If another such
object were placed not far from the first one, and the resonant
frequencies of both were the same, then the energy could be
transferred between them with very little energy lost to other
objects in the nearby environmental that do not share the same
resonant frequency. The transmitted energy, although
electromagnetic in nature, would not be referred to as "radiation"
since it is bound to the resonant objects. It is rather an example
of "near-field" physics. Soljacic avoids words like "antenna,"
since the process does not involve broadcasts of energy in the usual
sense. In contrast, the vast majority of energy radiated by
antennas is typically wasted and lost into free space, while only a
small portion is picked up by the eventual receivers. Instead,
Soljacic uses terms like "source" and "drain" in analogy with
transistors to describe the movement of energy. An exemplary setup
might consist of a transmitter in a ceiling and devices in that room
(e.g robots, or computers) being powered wirelessly by this energy.

electromagnetic transmitted energy

>would not be referred to as "radiation" since it is bound to the resonant objects.

All things resonant radiate - a fact of life

If the authors intend that the energy moves by any method, even by a
speculative means, resonance is immaterial.

>It is rather an example of "near-field" physics.

which is a characteristic of radiation

>Soljacic avoids words like "antenna,"

How do you make a chocolate cake when the recipe does not call for
chocolate? Use Cocoa.

Wes,

A bit of mutual citation, bit obvious isn't it when there isn't some
indirection like a few intermediate authors / articles!

Nevertheless, LB Cebik deals more with patterns, and I deal more with
the feed system, and of course the big picture means considering them
both. I happily link to LB for people to read some useful info on the
other aspect. Is that too cosy for you?

More importantly, if you found any faults with my analysis, let me
know?

Cecil,

What has become quite clear from this lengthy thread and the experiments reported is that what you seek is impossible. The design and physical configuration of the Bird 43, and probably most or all simple SWR meters, is such that the measurement is completely unaware of the external "environment". The Bird 43 correctly reports system mismatch, such as that from a load that differs from 50 ohms, but it ignores any artificial mismatch from the adjacent coax.

A report of the valid SWR *on that coax* will happen only by coincidence. The meter does not care about the length. Zero is just as good an answer as any other length.

And who would really care to know such a thing? The unknown of interest is generally a load or matching device, not the improper coax.

If you really need to know the "valid SWR" on the mismatched coax you are going to need a different technique and instrument.

73,
Gene

I mentioned in an earlier post that I had done some comparisons of true RMS response based SINAD measurements and average responding meters.

I have just rerun the test.

I have a receiver with 2400Hz wide IF , fed with SSG and connected to a HP334A Distorion Analyser. I have adjusted the SSG for 12dB indicated SINAD on the HP334A.

The HP334A's meter is boldly labelled RMS, but it is an average responding meter scaled for RMS with a sine wave.

I measured the output from the HP334A using a no-name true RMS voltmeter that covers the audio frequencies involved (trap there... some dont make it past power frequencies), and measured SINAD of 11.3dB.

I connected the HP334A output to a PC running FSM and measured the following figures for Vtotal and Vfiltered

total filtered
V Average 2708 679
V RMS 2753 763
V Peak 4287 2302

(The three detectors in FSM are all calibrated to read the same on a sine wave.)

The FSM measurements indicate a SINAD of 11.1dB RMS responding and 12dB average responding.

Overall, the two / three methods are reasonably consistent indicating around 12dB SINAD using an average response meter, and around 11.2 dB using RMS responding meters.

That suggests to me that using an average responding instrument may overestimate the SINAD by a little less than a dB. However, given the statistical variance of the noise, I would not be fretting about it, especially on an FM rx where it might only need a smaller change in C/N for that SINAD change.

I connected the rx to a Motorola R1013A which indicated 12dB SINAD (it is most unlikely to have an RMS responding ALC and meter).

Hi Bill

Well I quite happily ran a 6M loop inside a 15M one. Seperate feedpoints etc. In my case I was trying to use the same mounting points (trees).

I didnt check how effective they were but the TX was happy and I spoke to people on them!. Used 75r Q sections on each.

The 40 vs 80 might have some detuning effect on 40M and major pattern change due to the harmonic relationship. You can always try modelling it..

Bill Cherepy wrote:
"---can have a full wave 49 meter loop inside a full wave 80 meter loop---?"

Bill Orr, W6SAI wrote a book, "All About Cubical Quad Antennas". One topic is "Concentric Quad Antennas" starting on page 49. Bill Orr says: "Interaction between the antennas of a two-band Quad is quite low." Orr suggests separate feedlines for each antenna and making feedline lengths odd multiples of a 1/4-wave so that the open-circuit of the unused feedline will appear as a short-circuit at its antennas resonant frequency at its feedpoint. Thus the unused assembly won`t likely respond much at other frequencies.
Of course, antennas have a second resonance at about double their first resonant frequency. Having the open end of the unused feedline available, one could deliberately detune the second antenna to reduce interaction.

Best regards, Richard Harrison, KB5WZI

Hey. I'm newly licensed tech (studying for General). I looked up my questions in Handbook but could not find info. I am construct-ing a dipole antenna for 15 Meters from insulated 18 guage battery wire from the auto parts store. Since I will be going QRP for the first weeks or month, I am not worried about power handling capacity. But, will I have to upgrade my wire when I go to 50 or 100 watts output? Also, I have a question about the insulated wire: is the insulation an impediment to the functioning of the antenna on HF? Thanks for being patient with a newbie.

Thank you, Cecil. Very few here responded to my questions the way I had hoped, although there was some very good info in those responces.

I had wondered what the effect of inductance in the dipole legs would have on a balanced fed antenna. It now appears that to get decent results on 75M I don't need to do that, anyway.

I had not thought much about adding dropping wires to the ends of my dipole legs, as one fellow suggested, because the trees are so conical shaped that their lower branches would likely be in the way of the vertical wires coming down off the ends.

I guess I need to research the G5RV antenna. Someone else here posted a nice URL to a site on it and I will be perusing it more.

Cecil, I definitely can make my dipole 102 feet accross the top. I am guesstimating that I will need approximately 35 or 40 feet of feedline from the shack to the feedpoint. Do you see any issues with that?

Thanks, Richard.

My main concern was that trying to tune a 100 foot dipole on 75M
might cause problems due to the dipole being shorter than halfwave on
75M. From what I am now concluding from your comments, and others',
this probably won't be an issue?

Ed

Yes, my 100 foot length would be about 42% ofthe wavelength of my
lowest operating band, 75M.... perhaps it wouldn't be any problem for my
cheap MFJ balanced line tuner to feed it?

I appreciate your comments. I'm off shortly to study the website you
pointed me to. Thanks.

Short answers: 18 guage will handle 100 watt transmitter. Insulated
wire will provide no discernable effect to your antenna performance.

This is seriously bad, replying to one's own post... but.

It occurs to me a quick test to reveal whether a SINAD meter is RMS responding or average responding is to test it with a 1KHz square wave. I am not suggesting this as a cal procedure, just a test that is more sensitive to the meter response than noise testing.

IIRC, the Taylor series coefficients for a square wave are: all even harmonics are 0, the others are 4/pi/n.

So, theoretically:
- an ideal average responding meter should read (1-2/pi)% which is 36.3% or 8.8dB on an perfect square wave;
- an ideal RMS responding meter should read (1-(2^-0.5*4/PI())^2)^0.5*100% which is 43.5% or 7.23dB.

Does the maths make sense?

I observe that my R1013A indicates 9dB on a good square wave, and the HP334A around 35% (9.1dB)... so another indication that they are average responding. I expect the readings a little low because neither instrument has infinite bandwidth.

Gene, W4SZ wrote:
"The unknown of interest is generally a load or matching device, not the improper coax."

Bird says:
"The Model 43 THRULINE Directional Wattmeter is a portable insertion-type instrument which accurately measures forward or reflected power in coaxial transmission lines under any load condition."

I accept the above description as I`ve seen confirmation under many conditions.

Bird also says:
"Line section:
The line section is a high precision 50 ohm coaxial air line designed for transmission line insertion between the transmitter and the antenna or load. A socket is provided in each line section for the plug-in element with the desired power rating and frequency range."

The width of the instrument including connectors is given as 4.25 inches. This makes the preciaion coax section longer than its width or spacing. I conclude from this that it is capable of enforcing its 50 ohms.

Bird mentions cable lengths in regard to VHF measurements. They suggest that insertion and removal of the 43 with random length cables attached may affect the load match unless it is made exactly a total of 1/2-wavelength. In the 1/2-wave case, insertion and removal have no effect on the load match. I`ve done this countless times and attest to its effectiveness.

If there were other possible problems with Bird cable lengths, they would have appeared during the past 50 years and been reported.

Many folks use that loop and a tuner for multiple band operation, and
therefore the smaller loop would not be needed.

Hi Ed,

An antenna can be too long, an antenna can be too short. Somewhere
over the span of all the HF bands, one antenna qualifies for one of
those two conditions. The issue is can you cope?

A tuner can usually resolve the problem of match, but it cannot do
anything about line loss for certain situations. Using the ladder
line answers that.

Finally, unless you demand the point shaving of eking out every tenth
dB for contesting, the combination of a 100 foot doublet, a tuner and
ladder line will give you just as good service as a tuned dipole.

That's a very good length for 40m, 17m, & 10m. You can analyze the
antenna yourself by downloading the free demo version of EZNEC
from www.eznec.com. If you want, I'll send you a model of your
antenna so all you have to do is click the mouse.

Walter Maxwell of "Reflections" fame recommends a minimum length
for a dipole of 3/8 wavelength. 102 ft is 3/8 wavelength on
about 3.6 MHz so it should and does work well. That's the length
of my dipole.

Source record: 68755

Asimov wrote:
"The transmitted energy, although electromagnetic in nature, would not be referred to as "radiation" since it is bound to the resonant objects."

A mistaken idea is expressed above. Radiation happens from conductors carrying radio frequencies. Radiation escapes. That`s a definition of radio. It`s the energy that gets away. It may be hard to contain.

When a conductor is swept by r-f, the current which flows upon or within a conductor depends on its impedance. Unless the conductor is without significant reactance, little current flows. A resonant, and low-resistance conductor may have a large current flow, depeending also on the strength of the electromagnetic (r-f) field.

Induced current on a conductor will all be re-radiated if there is no loss to a load or heat conversion. There is coupling between source and receiving conductors. A synonym is mutual impedance. Maximum available power out to a load on an antenna is 50% of that captured. The other 50% is lost in the antenna`s source impedance (its radiation resistance). In other words, it is re-radiated.

Mutual impedance does not trap energy on or in a conductor or limit excitation of multiple conductors.

Necessity is said to be the mother of invention. Identify the greatest needs and you may forecast some invention.

Best regards, Richard Harrison, KB5WZI

I think this is close to the right answer, but for the wrong reason. I
think it needs to be evaluated iteratively, and I get an answer closer
to 34.3% or 9.3dB.

There is a free competition running on the Southgate Amateur Radio
Club's website.

The prize is a brand-new Icom IC-V82 high-power handheld transceiver,
kindly donated by Icom-UK Ltd

To enter the competition, you just need to answer a simple question.
The competition page can be found at:
http://www.southgatearc.org/competitions/ic-v82.htm

The competition closes on the 4th January, so there's plenty of time
to get your entries in. You can make one entry per day.

Good Luck!

ARRL has recently reported quite acceptable compatibility results in
some BPL programs they have been testing.

I forget the details, 68 years old and suffering from occasional 'old
timers disease', but the info should be available from ARRL.

It is possible that acceptable BPL technology has arrived!

No.

It's acceptable to the ARRL because they "notch out" the ham bands. This means that it interfers with everyone except ham radio operators so they wash their hands of it.

What will happen is as people complain about interference from BPL, operators will move the frequencies it uses to avoid the complaints. If they bother at all, an engineer will take a portable radio to the site, pull up the antenna and listen. If he does not hear English, he'll log that there is nothing to prevent them moving the notch there and that frequency will be used.

Since HF propigation changes from hour to hour and day to day, a frequency can still be in use but he wouldn't notice it. Eventually due to demand and no one complaining too loudly all frequencies in the HF band will be in use. By that time no one will listen to the few hams that complain.

My experience with a starting a Google boycott shows me that hams really don't care. The operator of one very popular site dedicate to ham radio and I discussed it and he said that they could not afford to eliminate the "Ads by Google" and gave me a polite rationalization of why they should do nothing.

This is called the boiled lobster effect. A lobster placed in a pot of cold water will be happy for the change. As the pot gets warmer the lobster gets drowsy. By the time the water gets hot enough to cook it, the lobster has been lulled into oblivion. That's what will happen with BPL.

It's already started.

Geoff.

Hi Fred,
The standard G5RV is a pretty good antenna for 80m, 40m, 20m, & 12m.
Not bad on 15m, but the SWR on the coax for 30m, 17m, & 10m is
greater than 40:1 according to EZNEC.

I have optimized my G5RV for 40m, 17m, & 10m operation by making the
series balanced section 36 feet of 450 ohm ladder-line.

Owen Duffy wrote:
> The article is at http://www.vk1od.net/G5RV/ .

Owen, that's the best G5RV article I've ever seen. When
anyone has questions on the G5RV, I'm going to point them
to that article.

However, it does contain an error. You say:

" ... it ... does not have acceptable feed performance on
any WARC bands"

Yet your own SWR data shows a low SWR point at 25 MHz. The
G5RV actually has a lower SWR on the coax on 24.95 MHz
than it does on 21.3 MHz according to EZNEC.

Also, someone is preparing an article showing how length
selection of the "matching section" using relays can transform
the G5RV into a truly all-HF-band antenna requiring no tuner.
After that article is published, it would be nice if you
included that information in your article.

Just found one and replied to your posting. You and Cebik
seem to disagree about 12m where you say it won't work on
any WARC band and he says the impedance at the twinlead/coax
junction is "Resistive (90-100 Ohms)", i.e. SWR=2:1

Gene Fuller wrote:
> What has become quite clear from this lengthy thread and the experiments
> reported is that what you seek is impossible.

Not true. The question has been answered and it surprised me. Only
a half inch or so of ordinary 50 ohm coax is required to ensure the
SWR on that half inch of coax is the same as the SWR reported by
the SWR meter.

I didn't ask the original question in a very understandable
manner because I don't know of anyone who understood my original
question.

> And who would really care to know such a thing?

History:
Reg and I were arguing about a year ago whether two feet of RG-400
was long enough to ensure that the SWR reported by the SWR meter
was the same as the SWR on the RG-400. I said it was but had no
references that covered the subject so had no proof. There was
no answer to my question forthcoming from this newsgroup at the
time, so I asked the question over on sci.physics.electromag. I
received an answer on that newsgroup but, unfortunately, didn't
question the math. The answer was one foot of RG-213 but the answer
was off by a magnitude due to an accidental shift in a decimal point.
The correct answer was about an inch to reduce the undesired mode
by a factor of 1/e^5, i.e. 1/0.2=5 where 0.2 is the conductor
spacing, e.g. estimated for RG-213.

The error was caused by using 2" instead of 0.2" as the
conductor spacing.

I mistakenly ran with the one foot answer but, wrong as it was,
proved that my two feet of RG-400 was long enough. Now Dave has
set the record straight and caused the decimal point error to
be exposed by Owen and me at about the same time.

The correct answer is surprising to me. 1/2 inch of ordinary
50 ohm coax is enough to ensure a 50 ohm environment in that
1/2 inch piece of coax, i.e. to ensure Vfor/Ifor=Vref/Iref=50.

Nobody else may care, but I learned a lot and thank everyone
who contributed.

Hello Owen,

Seems both average-responding and trms meters use rectifiers, so a
square wave input with perfect symmetry should result in BOTH meters
reading the same: an amount equal to the peak square wave voltage. Am I
confused on this?

Chuck

Cecil, bearing in mind Lord Kelvin, can you say what the error in the measured value of the SWR, or the reflection coefficient, would be if the (sufficient) two feet of RG-400 was reduced to 1" inch.

Reg.

Hi Richard,

I don'r know about that. For the un-notched signal, yes, where the
dominant component is the sine wave. However, not knowing how a non-RMS
meter may respond to the notched-out (predomanantly noise) signal, I'd thing
there is a possible cause for error compared to an RMS meter.

Not only that, but 1kHz is important because it is the standard and
usiang another freq, say 2kHz puts is on another part of the de-emphasis
curve and numbers'll change.

According to Dave's calculations, 1" of 50 ohm coax will
result in a negligible error in the SWR on that 1" of coax.

The myth: "Contrary to oft stated views, the Classic G5RV is not an all band antenna, it: does not have acceptable feed performance on any WARC bands;" Quoted from: http://www.vk1od.net/G5RV/

12m is a WARC band. The standard G5RV performs very well on 12m band. Therefore, the above statement is a myth. (Hey, this silly myth game is actually fun.) :-)

Wait a minute here. You're percents and dB is confusing.

I don't know about the 1-2/pi. It's been about a year or so since I went through all this for that QST article using a serise resistor in the power line to figure out power supply (and rig) power consumption - unfortunately ignoring the pulsed nature of capacitor input power supply current, BUT...

I don't remember the analytical expressions for these quantities. I'll use the common numbers...

For the meter that responds to average (63% peak - I think this is 2/pi) , but shows RMS which is .707 of peak (1/root2), the ratio for average input to reading = 0.707/.63 . For this I get 2/(2* root2)

Average of a square wave is equal to the peak.

So a 1 volt (pk) square wave should measure 1.11 Volts on one of these (sine average responding, RMS displaying) meters and 1V on an rms meter.

I think I did that right?

Nope. See my previous post.

A square wave has an average equal to the RMS equal to the peak. It's just like DC.

The "older types" RESPOND to average of a SINE (63% of peak) but display the value for the RMS (71% of peak), so they have a 1.11 correction factor to get from average to RMS.

When reflections are completely canceled, appear to have
disappeared from everyone else's sight, and you say they are
brighter than the sun (for you), who am I to argue? You have
created your own unreality and everyone who understands the
physics of 1/4WL thin-films in this universe laughs at you
every time you post that "brighter than the sun" nonsense.
In your calculations, you superposed powers which is not
a valid thing to do and you apparently haven't even
comprehended the error of superposing powers.

> No numbers, hmm?

Dave provided the numbers. Check his posting. Simply stated:
The unwanted mode is attenuated by 1/e with each increment
of length equal to the spacing between the two conductors.
If the conductor spacing is 0.1", the unwanted mode is down
to 0.00000001% in one inch. That's a big surprise to me but
I don't see any reason not to believe it.

That's the simplest way to look at it. The desired signal (tone) is
(approximately) 12 dB above the junk.

> Is the the input value in dBm on the test equipment the sensitivity of
> the receiver at 12 dB SINAD.

Yep. That's it! The INPUT level, which gives this special output
condition, IS the sensitivity.

When measuring sensitivity, you need some kind of a reference point and the
signal to noise ratio at the receiver output (after a fashion) is what is
used here. . If I recall correctly, way back, AM receiver sensitivity was
the input signal (with some standard modulation) which produced the rater
power output (audio) with the volume cranked all the way up.

> 73, Fred, K4DII

I for got about the 20 dBQ method. That's another reference for
sensitivity on FM receivers.

That's right Fred. It's explained up thread, but basically it is the ratio
of the un-notched audio to the notched audio. The "audio" is the result a
1kHz FM modulation at 60% of rated system deviation. Originally, for 5kc
ssytems dev., the 3kc deviation was 3.3kc. WHY is this at around 2/3
maximum? Well, in a well designed Tx, the deviation will get up to this
level before the deviation limiting clipper starts to clip and cause
distortion.

No time to read all the other posts, but in short...

You are proposing a slightly shorter than 1/2 wave dipole for 75. This should be no problem as it will have a little capacitive reactance and a tuner should handle it.

The G5RV is pretty much the same thing, except it has some feed line gymnastics to get a "fairly good" (50 ohm) match on many bands. This is nothing more than an "antenna tuner in feed line" which doesn't require a knob rather than one in a box which does. (:-)

My 40M dipole works on 30M as a slightly LONG dipole. [[It also works on 75 as a really short one, but not too good]]

Leaving aside the rectifier point which is arguable:

If we accept that the RMS responding instrument reads correctly on all types of waveforms, the issue is with the average responding instrument.

The average responding instrument is (usually) calibrated for the form factor of a sine wave, and its scaling in RMS is only valid for waveforms with the same form factor.

There are two cases to consider, the square wave, and the square wave with the fundamental removed. The form factor of both are different to the form factor of a sine wave, and more importantly to each other, so the average responding meter does not provide an accurate ratio of the (true) power of each wave.

Does that make sense?

Thanks Chuck, forgot all about RSS 181, even though I have type approval tested countless SSB transceivers to that specification. Interesting that it has not been updated since 1971. Note that he sensitivity is defined as that input that will produce 12 dB SINAD or that input which will produce at least 50% of the rated audio output. The fact is that most of the testing that I did was measured at full audio output, just below the threshold of audio clipping. I do not recall any unit where the receiver gain was a factor in sensitivity. Also note they still refer to "A3j", and not J3E, etc. All these old specifications are based on tube designs. With TDA2002 type audio chips, you could typically get 5W out at < 1% distortion. It was so easy to drop in an extra IF stage if you could not meet the 50% min audio output at threshold sensitivity.

Geoff.,

Your words not theirs. "They" (I'm in contact with "them") have
reservations and are aware of the outside-notch problem.
The advantage of this system (I'm not saying it's the solution or even a
great idea, but an attempt to provide an alternative in light of the
relentless push to do it regardless of interference potential) is that is
takes less energy to get from the pole to the house than down the whole
medium voltage power grid. The HomePlug(tm) protocol will be / is in homes
already, so even without this style of BPL, the garbage'll be in the air --
and not necessarily with the limited protection mechanisims (for HF users)in
this system.. It's an attempt to find an approach to satisfy both sides,
which no one else is attempting to do, including the his Ignorance at the
top.

> ...because they "notch out" the ham bands. This

There are much better solutions in the works... Again, I'm not a
proponent, just saying there are those who are trying to minimize the
problems with an, unfortunately, inevitable thing.

The thing here is that Motorola at least kept in contact with one of the
groups opposing BPL rather than just ramming it into a power grid and
totally iognoring all reason/physics, even appropriate complaints.

> ...If he does not hear English,
> he'll log that there is nothing to prevent them moving the notch
> there and that frequency will be used.

You mean if he DOES here Engilsh he will move the notch there and
the frequency will NOT be used? The notches go where the turned-off
carriers are so the residual energy gets attenuated even more.

No argument with the rest of this. BPL is an unfortunately ignorant
approach to a non existent problem.

Interesting that the article ignores the foreign systems which were shut
down, but then they were only given the party line...

>junction is "Resistive (90-100 Ohms)", i.e. SWR=2:1

No, I said:

"Contrary to oft stated views, the Classic G5RV is not an all band
antenna, it:
* does not have acceptable feed performance on 1.8MHz;
* does not have acceptable feed performance on any WARC bands;
* does not have acceptable feed performance on 28MHz."

Two main factors were in my mind in determining whether performance
was "acceptable", they were:
- the magnitude of the losses on this particular model in-band for the
band in question; and
- whether the losses changed rapidly on adjacent frequencies, such
that installations with small differences (eg height, earth parameters
etc) were not assured of acceptable losses.

For example, it is possible to tweak a G5RV a little to minimise the
feed losses on 10.1MHz, and they can be low enough, but it is a very
sharp notch and likely to be not realisable with seasonal changes in
soil moisture etc.

I have reviewed the specific case you mention about 25MHz. Two of the
feed arrangments are marginally under the criteria that I set, but
they are under it and for consistency they should have been included
in the "acceptable" category. Omitting them was an error on my part.

I have ammended the article accordingly Cecil, thanks for the
feedback.

It is important to keep in mind that the article is analysis of a set
of common feed configurations of a dipole at a specific height over
specific ground, and that the results may vary in other
configurations.

You're correct, of course, Steve. I was thinking the average-responding meter was calibrated to display average levels, but it is not: it is calibrated to give the rms value of a true sine wave with that average value. So the only way to measure the average value of a non-sinusoidal ac signal is to use an average-responding meter and correct the displayed reading as you have noted. Not relevant to the SINAD discussion but interesting.

Thanks for the clarification.

NO

Put it up. For a 40M dipole, I have insulated 20 guage (with the ends
threaded through the end insulators then doubled back and wrapped around the
antenns for about three feet, for easy length adjusting if needed).

Wes, I did take it as light hearted, and hence my response above.

I am not an academic, nor do I have the experience of that university environment, but I think there is probably more than a little humour to be had from examples of self-citation, mutual-citation, self-citation indirectly by n levels (more subtle than mutual citation)... etc.

Thing that had my head spinning was trying to follow the logic (I use the term loosely of course) of some recent threads.

Bob,
Hmmm. I don't think this is a worry either. I have had no protection (nor perceive a need) for this where the insulation ends at the feed point nor at the ends that are just cut (which wrap back on the antenna for about 3 feet for adjusting length. It is stranded wire with lots of opportunity for water egress. The insulation is very brittle after 6 years in the UV & other outdoor environment. I don't see what the problem mechanism could be; a bare wire gets really wet.
What are you thinking?

As a side note, and unrelated situation, aircraft wiring can burst into flames with help from water (Believe it or not) and insulation cracks, but in bundles of wire and where there is significant 400 cycle power distribution energy _between_ wires in a tight cabling bundle, not a single hanging wire.

>I think I did that right?

The problem is that while the RMS meter provides a true power indication on the square wave, and the filtered square wave (ie without fundamental), the average responding meter does not give an accurate power ratio because the form factors (RMS/AVG) of the two waveforms is different.

Don't overlook the fact that in most cases, insulation increases the wind resistance and increases the mass (weight) of wire antennas, so reducing the survival in strong winds, while not improving the radiation performance.

Further, the insulation will degrade more quickly than bare copper in all but the most corrosive environments.

Don't change your plans now... but something to keep in mind for the future, especially for long spans.

You might ask, if insulated stranded annealed copper is a poor choice compared to say single core hard draw copper or Copperweld, why do so many people use insulated stranded annealed copper? I guess it comes down to availability, and that amateurs seem to not design wire antennas to survive high winds.

The 18 gauge shouldn't present a problem, for Power, nor Loss.
It , however may present a problem, in the winter, if you get
ice loading (can streatch, and also break, if has enough stress
(extra weight) applied to it) , but, as far as qrp, on the low
bands, you may ve amazed at the dx you can pull in , even with
power in the milliwatt range, and, with a couple of the older
(10 watt) rigs, like the ft301-s, or the ft-7 (and kenwood,
Icom, and Ten-tec made them, too!), can work reliably several
hundred miles on 75-40 meters, and THOUSANDS on 20-15, and 10!
Have fun-- Jim NN7K

I disagree with that. It's inevitable because Google was one of three companies that invested $100,000,000 in Current Communications. If EVERY HAM boycotted Google and made sure they and their advertisers knew it, they would drop it like a hot potato.

Google exists because of their Adsense product. If advertising with adsense lost customers instead of gaining them, then advertisers would look for alternate ways to spend their money. If they did that, Google would not continue their support of BPL.

> The thing here is that Motorola at least kept in contact with one of the

I have not seen the technical specs of the Motorola system so I can't comment on it, but the rumor is that it does work and does not interfere.

> You mean if he DOES here Engilsh he will move the notch there and
> the frequency will NOT be used? The notches go where the turned-off
> carriers are so the residual energy gets attenuated even more.

Yes. If here he hears English, he will assume there is someone who can point to his power lines and show there is a problem. If he hears another language, he will assume that the people whom he will interfere with are too far away to walk up to his wires and show they are a problem.

> No argument with the rest of this. BPL is an unfortunately ignorant
> approach to a non existent problem.

IHMO exactly.

>
> Interesting that the article ignores the foreign systems which were shut
> down, but then they were only given the party line...

Yes, it has been a dismal failure just about everywhere it has been tested. It causes too much interference and works so poorly that no one could afford it without a big sum of money up front. If they make $10 a month profit from each customer it will take a long time and a lot of users to get back $100,000,000.

>> This is called the boiled lobster effect.

looking to the best option for putting up low band wire antennas. I'd like to put up something for 80 m with a bit of gain headed towards Europe etc.. I'm considering a half square antenna. But doing the math for the element says I would need something like 70-80 foot masts and I'm trying to figure out how to make that happen without full-scale antenna towers which would freak out the neighbors.

I think another option might be to do linear loading on the vertical elements of a half square and only go to about 45 foot for the tower elements. Problem being that most of the fiberglass masts I've seen only go to about 35 to 40 feet and some of them get pretty whippy (mfj)

another possibility I'm considering if I can build a fairly inexpensive metal mast to 66 feet (plus 10 feet off ground) is the Spitfire array http://www.yccc.org/Articles/Spitfire/sld003.htm

again suggestions for how to get 66 feet of metal up in the air would be interesting. By the way, I do have access to 3 inch aluminum irrigation tubing. Most of it has been broken into 25 foot lengths so if that would be useful, advice on how to couple shorter pieces together for good electrical and mechanical connections would be welcome.

I would appreciate any suggestions. also, don't worry about e-mailing me directly in addition to posting to the net. I frequently forget about web oriented access until weeks later whereas e-mail is in my face.

I have pretty much decided to just feed ladder line with a balanced
tuner rather than make a G5RV. This should give me more flexibility.

Thanks for the offer, Cecil, but at this time I will decline. I plan on just putting up as much wire as I can effectively mount between the two trees, about 100 feet, and just feed it at the center with ladder line. A new balanced tuner will tune the whole thing. I expect this to give me a bit more flexibility than the G5RV would.

That's the antenna I was offering to model for you. You will,
no doubt, run into some pitfalls, for instance an impedance
of 8 ohms or 4000 ohms that your tuner may not be able to handle.
EZNEC can predict such problems before they bite you.

As a data point, the MFJ-974 gives you a matching range of 12-2000
Ohms.

EZNEC can also predict your radiation patterns which are important
on the high bands if you want to hit certain areas of the world.
Rotating my dipole in AZ by 15 degrees made a lot of difference.

>I think this is close to the right answer, but for the wrong reason. I
>think it needs to be evaluated iteratively, and I get an answer closer
>to 34.3% or 9.3dB.

An analytical approach to solution of the problem.

A unit height square wave has a fundamental component of amplitude
4/pi.

To find the area under the filtered curve, I think we are looking for
the integral from 0 to pi/2 of absolute(1-4/pi*sin(theta))). I will
divide the integral at theta=asin(pi/4) to deal with the absolute
function since the problem function is positive from 0 to asin(pi/4)
and negative from asin(pi/4) to pi/2.

Here is some Perl to evaluate the ratio:

```
#find the zero crossing point
$theta=asin($pi/4);
#find the area under the curve
$area=$theta-4/$pi*(-cos($theta)+cos(0)); #first part
$area+=4/$pi*(-cos($pi/2)+cos($theta))-($pi/2-$theta); #second part
#divide by area under unit square wave
$ratio=$area/($pi/2);
print "Average response ratio is $ratio \n";
```

And the answer is 0.3430678471... or 9.3dB. It is about 9.4dB if you
only consider the harmonics up to 50KHz.

One of you mathematical whizzes might know a better way to put this!

Source record: 68615

This sounds similar to some cable I got surplus a number of years ago. The loss was surprisingly high at 7 MHz. I'm quite sure the reason is that the center conductor is made from several strands of very fine copper-clad steel wire. Although the copper is probably a sizeable fraction of the overall wire thickness, it's still thin in terms of skin depth at the lower part of the HF region because of the very small strand diameter. Consequently, significant current flows in the steel, which is very much more resistive than copper at HF. Loss at VHF is about what you'd expect from a copper center wire.

So I recommend checking the loss before using the cable at HF if loss might be important to the application. I used it as low-weight feedline for Field Day (I generally backpack my FD gear), and was prepared to accept the loss I thought it would have as a trade for the low weight. But I found the loss to be considerably greater than expected.

From: David <groups@orbitcoms.com>
Message-ID: <gY15f.21203$U51.10718@news-server.bigpond.net.au>
Source record: 68617

Hi,

I am in the process of making a couple of 9dB Collinear antennas for 920 MHz.

I was wondering if the diameter of the coax is significant.

The design is simply 1/2 wavelength sections soldered centre to braid with a 1/4 wave radiator at the top and a 1/4 wave sleeve choke and a few ferrite toroid baluns at the bottom. The original design uses RG58 coax but I find this difficult to solder in short lengths and the dielectric melts if the iron is left on too long. Instead I am using RG174 PFTE dielectric. The Vp for both is still 0.66.

Thanks for any info

Regards

David

yes, that's a very nice antenna design. However, if you notice the specification they want the center point of the antenna at 80 feet. like most hams I've got nothing even vaguely resembling 80 foot worth of antenna support. The best I can do is something around 25 feet but the trees are are not oriented so that I could get the direction I desire.

Source record: 68622

Owen,

[[[while I suspect the difference is so small that it makes little difference in the receiver sensitivity number arrived at, I proceed anyway.]]]

From your last two posts, it appears you/we have vastly different interpretations of what the question was. You talk about removing the fundamental from the square wave and this puzzles me. I do not believe the intent was to measure SINAD using a square wave modulation. Therefore removing its fundamental and measuring its RMS does not fit the situation.

My understanding of the issue was measuring SINAD with the older "Average-measuring-, RMS-reading" type (call it the "AVG-Type") of meter vs, a "true RMS" reading meter.

While I did talk about measuring a square wave with the "AVG_Type" meter, that was a digression only ment to show (what I think is) the difference for the previously proposed reference measurement. Namely try simply measuring a square wave for comparing the two meter readings, not SINAD measurements. I did this to show a calculation of how the two meters would read knowing the average and RMS values of _some_ waveform. I was thinking that I could do this for the two SINAD waveforms, but as you see here, I gave up...

Back to SINAD.
Therefore, the issue I was addressing was the following:
(for the normal SINAD technique, 1 kHz sine wave tone):
A- Assume the RMS meter gives the "correct" reading.
B- What does the "AVG_Type" show on the display/scale?

So, B has two parts.

1- What does the "AVG-Type" read for the un-notched signal, and
2- What does the "AVG-Type" show for the notched signal.

1- As a first approximation, lets say the un notched reading is dominated by the sine wave. With this assumption, they both read the same. To refine this estimate, I am unable to assess, easily, the effect of the noise on either measurement except that the True RMS mwter will give an indication of the total tone and noise power (actually Erms^2). As a first approximation, we could say that the "AVG-Type" reads the average of the sine plus the average of the noise voltages...and my estimation powers peter-out right there.
2- What does the "AVG_Type" read on the noise (notched signal)... yep, peter once again.

Therefore:

GOTO [[my statement in brackets above]]

Then there's the pronunciation. Some say "sin' add" and some say "sign' add". We said SIN add.

Nice exercise, time for me to move on to other things.

2626. Feedpoint of a Half Square

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-18 16:28:32 UTC
From: Jim Leder <k8cxm@spam.fuse.net>
Message-ID: <e1bfe$435522a8$42a1c3a6$17874@FUSE.NET>
Source record: 68623

For years I've always fed my 30 meter Half Square at a top corner, and it's done a reasonable job in my opinion. Recently I've discovered 2 Eznec files, one for a Half Square and another for it's big brother, a Bobtail Curtain. Both show the feedpoint down just a little bit on the driven element vertical, and NOT dead on the corner. I've studied both Eznec model outputs (corner feed and not corner feed) and indeed the different feedpoint does show a little more gain, about 1.5 DB without altering the antenna impedance much. The one I modeled for 30 has the feedpoint down about 2 inches from the corner. Is what I am seeing accurate? Or, is this just another Eznec anomaly? I realize that 1.5 DB isn't too much to worry about, but if I should make another one, maybe I should alter the feedpoint. Opinions? Thanks.

Both. For instance the resonant impedance of a G5RV on the lower
part of 80m is usually about 8 ohms. If the feedline for a one
wavelength dipole is 1/2WL, the impedance will be about 4000 ohms.
The feedline impedance seen by your tuner is somewhat unpredictable
and EZNEC can tell you what ballpark impedance to expect. EZNEC
has saved me an enormous amount of time - 10 minutes of simulation
Vs 10 hours of antenna erection time.

For an antenna like the half-square, I would trust the EZNEC results
as long as you didn't violate any of the EZNEC guide lines.

I once violated the EZNEC guidelines and got an omindirectional antenna
with 20 dBi gain in all horizontal directions. :-(

Another possibility is to feed the half-square at the lowest point
with a matching network to match the high impedance.

Another thought just occured to me - that a 600 ohm feed point must
exist somewhere down the vertical section. Of course, balancing the
currents at that point would be a challenge.

The loss in a switched transmission line tuner is somewhat greater
than in a conventional tuner which can be adjusted for an exact,
low-loss, impedance match.

OK. I'll take you up on the offer, afterall. Figure 100' of #14 copperweld, centerfed with 450ohm ladderline or with 600 ohm open wire line (2"). Height should be about 45' at ends and 35 feet center. Length of feedline is projected at about 45 feet.

I'll go with the 600 ohm wireline feed if I can find it, otherwise, the cheap 450 ohm plastic stuff for now and build wireline next summer.

Not real concerned with the patterns of anything above 40M. I'm mainly interested in 80/75/60/40M use. I'll take what I get and see how it goes..... might be nice to see 20M and 10M patterns, though. Thanks.

Sofasurfer wrote:
"What is a follower?"

A follower is an amplifier in which the output signal voltage is nearly the same as it "hollows" the input voltage. Its purpose is to reproduce the input voltage, but make it available at a lower output impedance. Thus it has power gain although it has a slight voltage loss. Its input impedance is high because it has a very large inverse feedback. This gives it a wide frequency response as well.

Suppose you have an ordinary r-f transistor, almost any will do, that works well at 1 milliampere of collector current, and it has a current gain of 100. We have a d-c power supply of 12 volts.

We want to drop about 6 volts across the emitter resistor so our signal can have equal up and down swings. Ohm`s law tells us that a 6000-ohm emmiter resistor will drop 6 volts with 1 milliampere through it.

We can set our forward bias with a pair of 60,000-ohm resistors connected in series to give about 6 volts at their midpoint for the transistor base connection. These are low enough values for stability. That`s all there is to the d-c design.

The follower will present about 30,000 ohms load on the 5,000-ohm AM broadcast antenna whip. The transistor loading on the whip is negligible being about current gain times the emitter resistance.

The follower will present a very low output resistance to its load, the line to the radio it feeds. It is much less than the 6,000 ohm emitter resistance due to the inverse feedback around the transistor.

Capacitors large enough to have negligible reactance at the r-f loads should be used to couple the input and output of the follower to avoid d-c upset. Match transistor and power supply polarities. Transistor manuals have sample circuits.

Best regards, Richard Harrison, KB5WZI

600 ohm open wire line is available from W7FG [800-807-6146].

50 feet $23
100 feet $40.

I've used it for years at the KW level. No problems.

I'm just a satisfied customer and have no financial interest in their
business.

>removing its fundamental and measuring its RMS does not fit the situation.
>

Some discussion arose about the extent of errors when using an aveage
responding meter to measure SINAD (compared to a true RMS meter).

My experimental evidence is that when measuring SINAD on a 2.4KHz wide
receiver at SINAD=12dB, the error is less than 1dB. Of course, it will
be less for higher SINAD ratios, and worse for lower ones.

I offered that a simple test of whether a SINAD meter was average
responding or true RMS responding, was to measure the SINAD of a good
square wave. The average responding meter will indicate about 9.3dB
whereas an RMS responding meter will indicate around 7.3dB.

I think we both understood that.

>
>Back to SINAD.

>2- What does the "AVG_Type" read on the noise (notched signal)... yep, peter
>once again.

As I stated above, and you stated, the comparison will depend on the extent to which the sine wave dominates the total signal, and so will depend on the SINAD being measured. I suggest that it will also depend on the noise bandwidth.

Repeating, my experimental evidence is that when measuring SINAD on a 2.4KHz wide receiver at SINAD=12dB, the error is less than 1dB.

At the end of the day, it doesn't matter that much for normal applications if the SINAD meter is average responding, they appear to overestimate the SINAD, but by a very small amount.

>

I'm currently building a VHF APT image receiver for my vehicle, and need a suitable antenna design that is rugged enough to survive the rigors of being hit by hail and strong winds. It also needs to be relatively compact because I need to fit other antennae on the roof too. I was thinking some sort of helical. Anyone got suggestions of what would be best? Thanks,

David

David

I have some experience with APT imaging and antennas for NOAA satellites.
You can contact me at my E-mail address for more info and pictures.
I wouldnt be optimistic about being able to get good images with an
antenna that is permanently mounted above the top of a car.
Are you aware that Walter Maxwell frequents this news group? He has to
be the best source of guidance on APT antennas *anywhere*.

In my experience, you can more precisely control the length of the tubing
than with a braid shield. There is some mechanical rigidity advantage, as
well, although that isn't a big factor if you use some sort of dielectric
tube to contain the antenna.

Hello guys,

I am building an RF tag that will transmit some data using a microcontroller and a 433 Mhz transmitter. But I do not want to place any buttons on the device nor have it be on at all times. So I was wondering is there a way to create a magnetic field at the source to generate an induced current in this tag to perhaps flip a switch to turn on the internal battery? And once the tag is out of the fields range the switch will open again?

I know systems such as the Sunpass or other electronic toll payments use something like this.

If anyone has any information on how this can be done, please help.

Thanks.

Some of the passive RFID stuff powers the card from the incoming carrier
wave -- but I have no direct experience with them. I don't know how
close you need to be other than having heard of them being used on
railroad cars passing a fixed installation.

Hi!

If I was to take yagi antenna for 1.2 gHz and then double the length of each element. Would that work on 2.4 gHz?

Newbie here. Doesn't higher frequency = shorter wavelength? Therefore,
shorter elements? Also, probably need to adjust spacing of elements per the
formula.

No.

If you begin with a Yagi antenna made for exactly 1.2 GHz and *reduce*
the element length, element diameter, and element spacing all by a
factor of two, it would work at exactly 2.4 GHz. That's assuming that
the effect of the boom is negligible. If the boom is large enough to
have an effect (typically the case), you'll also have to reduce the
diameter of the boom by a factor of two.

There's an infinite number of other combinations which will work; for
example, you can leave the element and boom diameters the same and
change only the spacing and element length. But then the spacing and
element length will need to be changed by some factor other than two,
and there's no simple way to calculate the factor.

No!

A Yagi is a moderately complex design. Generally a computer, or computer generated graphics and length tables are used for element length, spacing and boom length.

A 2.4 GHz Yagi would be close to 1/2 size, in all dimensions, of a 1.2 GHz antenna.

Your best bet is to buy a commercial antenna for your application.

Hi folks,

I have some questions. If I had two power amps at 15W each, 2 feet apart, and they are connected to two similar isotropic antennas, would the two far-field patterns add up? How would I calculate the power received by a receiver at a certain distance?

I wonder since each antenna will have 0dB gain, then ideally the loss that I would need to take into account would just be free space path loss, eh? Will the antenna patterns change in terms of beamwidth and gain? What other changes/factors do I need to know about?

Thanks!

Remember that the relationship between wavelength and Frequency is
defined by the equation ---

c = Lambda X Nu

where
c = 300,000,000 meters per second
Lambda = wavelength (in meters)
Nu = Frequency in cycles per second

Thus solving for either lambda or nu reveals an inversely proportional
relationship between the two.

Consequently as the number of cycles per second (frequency) increases,
the wavelength shortens.

If they are ABSOLUTELY in phase, the far fields will add.

Typically, the fields will not be in phase, unless the signal SOURCE and ALL cables are precisely controlled [phase locked and absolute phase velocity controlled], and the resulting pattern will be the vector sum of the individual fields. a distorted pattern will result.

I guess a magnetic reed switch wouldnt be sensitive enough? This device that is often used for door and window alarms by moving a magnet towards or away from the switch. I am guessing that 20-30mm is the normal actuation distance. No doubt you could increase that distance by using a stronger electromagnet

Making my brain work again!! (So some of this may be through my hat!)

The far field pattern would no longer be isotropic. You didnt specify the frequency in use but genenerally speaking you would get more radiation perpendicular to a line between the two antennas than in line with them. As you go lower in frequency this effect becomes less and less. As you go higher than frequencies where the distance between become more than a wavelength (or so) the pattern will tend to break into more than one lobe in each (general) direction. This assumes of course that the antennas are also being fed in phase, probably from the same transmitter.

This pattern is a result of the addition and cancellation of the voltages due to the phase differences. If your antennas dont run from the same TX and the freq/phase is changing the pattern will be changing at the rate of the freq difference.

Calculate the power in theoretical terms of an AC voltage either perfectly in phase (ie twice) or if some phase difference occurs, being somewhat less.

I am sure that you know about the squishable rubber ball analogy of antanna radaition patterns.

Modeling your setup through 4NEC2, EZNEC etc will give you a far better appreciation of the outcome. I'll admit I dont know how to input an isotropic in these pgms though.

As a general rule of thumb when one combines two antennas (usually ones with gain) at the correct spacing you get inbetween a 2dB and (just under) 3dB power gain increase in the desired direction. As you get close to the maximum gain possible though you also see "extra" sidelobes that depending on your use may be undesirable.

Hope you find this of some use and not too confusing!

Cheers Bob VK2YQA in W5

why not use one of the readily available systems that has the problems already worked out? there are rfid tags that you can program with your data to track things, and there are the smart rf activated credit card type devices for users. both of these use a short range hf signal that is received by the tag, converted to power the internal circuitry, then to send out the data burst to identify the tag or card and dump their data. the card is only active while in the activating field, otherwise it doesn't have any power source. electronic toll payment systems usually use a more active device since they have to work over longer distances, most of these have a battery in the client device that powers the receiver... the receiver may only come on for short checks every second or two to see if it is in range and needs to send it's identification and data so battery life can be very long.

With considerable contortions of phase math, or simply by using EZNEC.

Unfortunately, EZNEC does not model a isotropic radiator (but you
don't really have two of them anyway, do you?), so you may have to
slog through the vector additions. They are not that very difficult,
conceptually (although it seems to have baffled the crew so far).

Phase at a frequency is equivalent to distance, and you already know
both the frequency and the distances. Beyond this, it is no more
difficult than making a three bank shot in billiards.

2670. Messed-Up Radials Can Generate Spurious Emissions

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-20 18:57:21 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <kvpfl1dgvg5575f7l0chd91s886nu3anp7@4ax.com>
Source record: 68567

Messed Up Ground Radials Can Generate Spurious Signals

In 1948 I was the consulting engineer for the proposed first AM broadcast station in Mt. Pleasant, Michigan, obtaining a construction permit and license for WCEN, 500 watts on 1150 KHz. Using a National HRO receiver, I was performing a hands-on search for an available frequency for the new station, when I encountered an interesting and unusual signal that was entirely out of place in the AM broadcast band-a CW Morse-code station illegally transmitting five-letter-word code groups at 30 words per minute. The illegal signal was S9 +40 dB on 1297.8 KHz, producing a 2200 Hz beat-note with the 1300 KHz frequency of WOOD, Grand Rapids, thus producing a an audible CW signal with the receiver BFO disabled.

The format of the coded messages appeared to be military, IDing as NSS. We know that NSS is the flagship station of the U.S. Navy in Annapolis, MD, but in the AM broadcast band? It appeared that either an NSS transmitter was producing a spurious emission, or a station using NSS as a fraudulent call sign was operating clandestinely in the AM broadcast band. I deemed it important to find out which.

As a former FCC monitoring officer at the Allegan, Michigan monitoring station, the next step was to report the situation to the Allegan station. Although Allegan was 90 airline miles away, the monitoring personnel there could not hear the spurious signal, even though it was S9 +40 dB at Mt. Pleasant. I let the FCC monitors hear the signal through the telephone, but they still heard nothing on their receivers tuned to 1297.8 KHz. Thus the signal must be of local origin near Mt. Pleasant, and not from NSS. However, to be on the safe side, FCC notified the Navy of the spurious signals, and the NSS operators began combing all their transmitters for spurious signals, and found none. The situation is now becoming even more strange.

I then copied five minutes of the coded text and sent a copy to the FCC, who relayed it to NSS for comparison to their transmissions. The situation is now both perplexing and frustrating, because the text I copied on 1297.8 KHz agreed exactly with a transmission that had been made by NSS. How could that signal have been transmitted on 1298.7 KHz if no spurious signals were emanating from NSS? But it's not likely to have been a fraudulent station. What then?

A partial answer came shortly thereafter. As I resumed the search for a useable frequency for the new station, I proceeded downward from 1298.7 KHz, going through 1280 KHz and hearing WFYC, Alma, 1000 watts, 15 miles away, also S9 +40 dB. But on continuing further downward I immediately came across another S9 +40 dB thumping CW signal. I switched on the BFO and discovered the CW was also a five-letter-word coded transmission at about 30 wpm, the same as NSS. I retuned to 1298.7 KHz and the NSS signal was also there, as before. So I cranked up a second receiver to monitor both frequencies simultaneously. Surprise! Both frequencies were showing identical simultaneous transmissions. I then measured the frequency of the lower-frequency signal-1262.2 KHz. Voila! The higher CW

frequency was 17.8 KHz above WFYC's 1280 frequency and the lower CW frequency was 17.8 KHz below WFYC's frequency. A quick reference to the Berne frequency listing showed NSS assigned to 17.8 KHz. This situation now appeared to indicate something very wrong going on at WFYC. The low-frequency world-wide ground-wave signal from NSS was apparently somehow mixing with the signal from WFYC, and producing the 1297.8 and 1262.2 sum and difference frequencies. But what non-linear device in WFYC's system could perform that mixing? Don't know, but I reported this new information to the FCC and that was the last I heard of the situationï¿½untiliï¿½

Fast forward now to 1955. I was now employed as an electrical engineer at the RCA Laboratories, the David Sarnoff Research Center in Princeton, NJ. An assignment took me to Washington, D.C. to attend the annual conference of the NAB, the National Association of Broadcasters. President Dwight D. Eisenhower gave the keynote address. However, one of the technical forums was presented by Jack Young, Chief Engineer of the RCA Broadcast Division. His topic was on the solution of mutual interference between two broadcast stations in Los Angeles, KFI and KNX.

It seems that in a section of the Los Angeles area it was impossible to hear one of these stations without hearing both simultaneously-when tuned to 640 KHz for KFI, both KFI and KNX were heard, and when tuned to 1070 KHz for KNX, both KNX and KFI were heard. Young was assigned the task of determining the cause of the interference and eliminating it. To make a long story short, he discovered that there were ancient and rusty oil well derricks in the affected area. Currents from both KFI and KNX transmissions were being induced in the oil well towers, and the rusty joints were acting as mixers for the two frequencies, producing both the sum and difference frequencies, as well as re-radiating both signals on their original frequencies. When the derricks were removed the interference stopped.

So how is this incident relevant to the NSS problem? Well, at the conclusion of Young's presentation I had the opportunity to talk with him, and because of the similarity of the problems, I told him of my discovery of the NSS signals appearing in the AM broadcast band. Talk about coincidences! He was surprised and excited to learn that I had discovered the NSS problem at WFYC, because he was the one assigned to determine the cause of the problem. He had never been told how that problem originated, or how the problem had been discovered.

He then explained that he had found the ground radial system under the WFYC antenna a horrible mess. Cold solder joints throughout, and far ends of the radials hanging loose in the water of the nearby Pine River, establishing the non-linear mixer condition that resulted in the sum and difference frequencies being generated between the NSS and WFYC signals. Cleaning up the messed-up radials ended the appearance of the NSS signals in the AM broadcast band, thus concluding an interesting journey.

Hi Walt,

I want to point out that your story has all the elements demanded of a
well written English composition. Some engineers who've been
horse-whipped through bone-head grammar classes bristle at the topic.
However, one simple lesson was probably lost (given it appears so
seldom here) in that punishment. A story (or any posting) needs:
a beginning;
a middle;
an end;
and should be have no spelling errors to speak of.

You've surpassed those simple elements by a consistently engaging in
good yarns.

Thanx,
Richard Clark, KB7QHC, B.A.

No. It would work at 600 MHz.. You went the wrong way.

If you cut ALL dimensions in half it would work at 2.4 GHz.. However, ALL dimensions include element diameters, boom diameters, element lengths and spacing.

I just recently read that a good Preacher should follow a similar structure:

A Good beginning
A Good ending
And as little as possible in the middle

Oh well !!!

I'm a part-time GED teacher. Writing is one of the most difficult
GED tests as it is not multiple choice. We teach the following
format for the writing test.

A beginning - a one paragraph statement of a principle or premise
A middle - three paragraphs based on three major points of argument
An end - A one paragraph conclusion summarizing the three points

The people in Austin who grade the GED writing tests like that format.

Cleaning up the messed-up
radials ended the appearance of the NSS signals in the AM broadcast
band, thus
concluding an interesting journey. .....

I think a lot of the MW garbage I receive on 160m, etc, is
generated much the same way. I've even seen people say
that semi corroded stranded copper wire, even insulated
can cause problems like that. And...I've been seeing stronger
and stronger MW energy here every year it seems... I'm starting
to wonder if the standed wire theory may not be too far fetched,
as most all my wire is stranded, and most is getting some age
on it. I also seen to notice even the water heater or pipes seem
to generate spurious MW energy.. Been driving me crazy the last
few years, and seems to be slowly getting worse.
Not to mention all the other sources of trouble like fences, guy
wires, bad connections, etc.
I don't doubt bad radials could cause that for a minute...I've seen
things like that around here in mildew city from all kinds of bad
connections.. Once had a bad "rf in the shack" problem...Turned
out to be nothing more than corroded/rusted balun hardware at
the antenna feedpoint. Cleaned that up, bingo, all gone. MK

IMD is going to be the least of our problems as the proliferation of
garbage-generating devices continues.

Soon your toothbrush will have an RFID tag, a switching power supply
and a bluetooth link to the toothpaste dispenser.

The tires on your car have RFID tags that will be queried when you
drive by a cell phone site and your GPS-enabled cell phone will report
your speed and a ticket will emailed to you automatically. No need to
respond though, your credit card has already been billed and your
photo is on the perp website.

Interesting proposal.
Interaction between the 2 would depend on several factors.
Your only stipulation is that they are 2 ft apart, so...
The frequency would matter and [[Relative]] lengths of coax to each antenna
would also matter.
Its possible you could have a phased array.
Under certain conditions gain could be broadside to the two,
in some other conditions, gain could be endfire.
Its probable, though, that all you have

is a mess.

I'm not sure of the physics involved but when 2 oscillators of nearly
the same frequency are brought within a certain maximum distance of
each other, their frequency and phase will lock together suddenly. You
can experiment the effect with walkie-talkies. I'll bet the same
effect will occur with your transmitters.

I learned the code at a very early age. When I was an op at AM BC station WMFJ Daytona Beach in 1940 we had no teletype for gathering news, but had a contract with Press Wireless for copying WCX/WJS Brentwood, NY. I copied the news every day for broadcast. The code speed was 35 to 38 wpm.

>I noticed also you referred to frequencies in KHZ. But shouldn't that have

I understand your thoughts on this, but if I had used KC in a current piece like this one, someone would surely say I should have used KHz. So either way someone would say I should have used the other form.

>
>Thanks!

Simple answer. First simplify. Two power amplifiers only cloud the
issue. We could say they are perfect ones and leave it at that but
it makes no difference if we just leave them out.

Assume those same isotropic radiators are feed by an inphase (0degree)
power splitter. What we have then is a pair of isotropic antennas as
an array. at low frequencies it will appear to be a fat radiator, and
at some frequency it will start to appear directional.

Assuming the frequency is high enough (around 5mhz) it will have
measurable directionality. At various points in space around those
two antennas the measurment antenna will recieve different amounts of
RF with varying phase. Why, the distances are with notable exception
unequal. The only place in space that will have the full radiated
power is a plane center between the two radiators and perpendicular
to the line between the two radiators. All other places there will
be a phase difference due to time/distance from the radiators and
measurement antenna. Those places will recieve less than full radiated
power due to the phase difference. The exact power is related to
antenna seperation and operating frequency.

Now if we pick a frequency, say 123mhz, which has a wavelength of
around 8 feet. The pattern (and gain) of the phased array (two
antennas feed in parallel are a phased array) will be similar to a
dipole in free space. For other frequencies the results will differ.

The exact answer obviously is frequency dependent and position
dependent. The exact field strength at a point in space is power
and location dependent. There is a standard calculation for path loss
that can be applied one you know the "gain" or "loss" of the array of

radiators in a particular direction

Well, it should've been "kc/s".
More 'short-handedly': "kcs".
A Hertz is a "cycle per second".

So can a weak alligator clip on a simple homebrew antenna tuner!

Several years ago I was operating CW while my wife was using a "glass TTY" to a remote computer (that shows how long ago this was), when a policeman (who was NOT a ham) knocked on our door and said I was causing lots of RFI and TVI. After thinking "I'm on CW; who would have been able to identify me?", I called a nearby ham. Yep, he said I was interferring on EVERY frequency he could check (AM, FM, TV, ham, etc.!), and since he couldn't phone me, he had called the police.

So I got back on the air and, with his help, started wiggling everything from the transmitter output toward the antenna. The culprit was a rather weak alligator clip in my homebrew antenna tuner, and that poor joint was producing harmonics from DC to daylight!

Hi:

Can anyone put me on as to where I may purchase a small 2.4 gHz
transmitter for sending video from about 1/2 mile.

Bob

Question. Do you guys *not* have surplus military equipment around? Surely!!
A hydrolic or pneumatic mast, or even a handrolic mast makes a good
support for wires and the like.
In the UK we have plenty of ex MOD surplus gear for sale in various
guises. Pump up masts used to mount lights, television stations/film
sets use them, and so do the military for Ahem, mounting antenna's.
Do a web search, you might be surprised what turns up.Dave

The author does not have a published email adress. I sent a rather scathing letter to the public editor of the Times, asking him to forward it to the author of the article.

I receiced an automated response, but nothing from a real person.

It really was a "puff" piece, a combination of press releases masqerading as a real article. Articles such as this make one question the quality of the Times as a news source.

Geoff.

C'mon Walt, you can do better than this 'weak' response.

You could define a new term. One that includes CPS for historical accuracy, and also includes Hz for contemporary usage. What about combining both into a new contraction, 'CZ' ? ;-)

Hi Walt,

Enjoyed reading the story. Thanks!

I live about 1/2 mile from a 50 kW broadcast station
on 1360 kHz here in West Phoenix/Glendale and am
within 5 miles of another half-dozen running 5 - 20 kW.
Recently I became quite aware of a bad splice in the
wires on my 80/40-meter dipole through the appearance
of mixing products from the broadcasters all up and
down both bands. Of course, I also saw the problem
on transmit, having one value of SWR at 5 watts and an
entirely different one at 500 watts. I hate to think
of how many "mystery signals" I was generating in the
process of getting that bit of test data! I keep telling
people I am going to cut that bad splice out and patent
it. How many mixer diodes do you know about that can
handle half a kilowatt.

73,
Jim, K7JEB

That would be doubly redundant. :-)
It would be the equivalent to saying "kilo-cycles per second per second".
Some sort of "FM propagation", I suppose.

A rubber ball represents the radiation from an antenna. ie perfectly spherical for an isotropic antenna. You can think of the field strength of the signal as being proprtional to the ball's radius.

When you put gain into the system you take the same amount of "power" and "squash" it into specific directions. You take from the direction you dont want radiation in and put it into the direction you do. You never get something for nothing and gain always implies directivity, even if that directivity is undesirable.

Okay?

I had a similar problem with a W2AU balun. AM stations all over the place. The balun "eye" bolts were severely corroded. Replacing the balun with a stainless steel version eliminated all the AM junk. I notice that W2AU baluns are now advertised as having all "Stainless steel" hardware.

Debate all you want, here's the scoop.

The answer to your first question (add?) is Yes. That is how multi-element antennas work, regardless of the element shapes.

For your second & third question (how to calc &pattern, beamwidth, gain):

With the described "one transmitter feeding two antenna" system you have nothing more than a phased array. Using two amplifiers is not important as long as you use good techniques connecting everything and match impedances _when both amps are transmitting_. That is if, in the first approximation, you have all the power from each amp going into the respective antenna. I suspect this is a valid assumption for the original poster. I'll speculate that this will be harder with only a splitter (no amps) due to the mutual coupling in the antennas and the impedance change therefrom, but matching things removes this complication.

Gee... do isotropic antennas have any mutual coupling / impedance??
Seems there could be for voltage only. anyway...

The relative phase of the two antenna currents will create the pattern (by summation in the farfield) [[regardless of the shape of the "iron in the sky" as I call it]] I believe (and Lew can corroborate or dispel) you can use EZNEC to get an idea what will happen by looking only at the horizontal plane, or vertical view of two verticals; 1/4 wave should do. This is the "plan view" or the view from above, where the verticals look like two dots. This should represent the view of the two iso's that looks the same (two dots).

With equal power and in phase current, you'll have a figure eight with the nulls broad-side and the depth of the nulls will depend on the frequency... starting from lower freq, at a frequency where the spacing is 1/2 wave, the nulls are deepest and as frequency increases, the pattern will develop more and more lobes/nulls.
IF the two antenna currents/powers are not the same, you should also be able to model this in EZNEC as described and the nulls will not go to zero as expected (well, by me at least).

Looking at the two iso's from the endfire direction (the two iso's look like one dot)..lemme think here...
Oh yea, you'll see a round pattern (perfect circle) of varying diameter as you vary the relative phase/amplitude. This will be equivalent to looking at it at only one angle from the plane equidistant from the two dots. Hard to describe, easy to imagine. As you change the angle of this cone (similar to viewing pattern at differing radiation angles), the circle also changes diameter.

SO... The "gain" will vary depending on Frequency, relative phase of the
two feeds and relative power of the two feeds. I don't thing path loss is
considered in pattern calculations since it is the same for all components
in the field by the time you get to any distance.
Post some pix.

OK, dispute away, I'm done.

Any comments Lew?

Regards, Steve, K,9.D;C'I

I'll only say that it is interesting that the first comments were about the grammar not the content.

Interesting story Walt. That's what I call an ending!

Brief story 1
The apollo recovery ships had problems in the radars from high power HF transmitters and the rusty deck railing chains.

Brief story 2...well not so brief.
To solve a problem in a 150MHz car telephone in a Caddy and one on a motorcycle, I developed a method for finding what I dubbed "environmental desense" of a similar nature. This amounted to the transmitter being modulated, in its _field_ by near-by noisy joints in the car body or the motorcycle seat springs. This produced virtual noise sidebands on the transmitter. This "modulation" extended out to the receiver frequency. The receiver used the same antenna, thus easily picking up this new "noise modulation.
This is an extension of what I had called "the Screwdriver Effect" in my early 2-way repair days. you are listening to a rather close transmitter (or maybe not so close) and you simply rub a screwdriver across another nearby piece of metal and you hear noise on the received signal. Same effect - field modulation.
To explain in more detail...
1- EVERYTHING conductive is an antenna (receiving).
2- Everything has RF current in it from every transmitter (even YOU).
3- These "everythings" therefore produce small RF fields of their own, from these currents.
4- These fields sum with the original field.
5- If two of these "everythings" come into contact, there can be a change in current due to the new physical arrangement (current through the new connection)
6- This change also changes the resulting fields from the "Everythings"
7- This changes the total resulting field.
8- this is just like a change in the original field and just like a change in the transmitted signal.
9- SO... this is received just like some similar modulation on the original transmitter. Try it, but the screwdriver part has to be near the receive antenna and the main signal not so strong that the noise is too far down. 2M FM may the best place to try.

Noisy screwdriver contact...noisy received signal

As I see it, Jonesy, kc = kilocycles, but we think of it as kilocycles per sec. kc/s = kilocycles/sec, which accurately specifies it as such, so it is not redundant.

Therefore, KHz is also proper, but KHz/s more accurately specifies it, and is also not redundant.

But aren't we being a little picky picky?

Walt

Actually, the Hertz is is defined as a unit of frequency equal to one cycle per second. That would mean the KHz/s is redundant. But you're right - it is picky unless the meaning isn't clear from the context.

KHz/s is a sweep rate.

Greetings,

You are invited to download and use the new version of WinCAP Wizard. The default download is known as QSL-ware. Which basically means freeware. <G>

This QSL-ware version provides unlimited point-to point and NCDXF beacon predictions, prefix search, numerous prediction views and more.

www.taborsoft.com

The registered version adds coverage analysis and user batch prediction modes. A 60-day trial key is available upon request.

If you use a competing tool, not to worry, they can surely add a few of the new features. <VBG>

Cheers,
KU5S

It is _not_ a pluralization. It is k(ilo)c(cycles-per-)s(econd).
The scientific notation for "X per Z" is "X/Z". Ergo, "cycles per
second" (cps) is "c/s". Thousand(s) of cycles per second is "kc/s".
The crude shorthand commonly used in ham radio is (was) "kcs"(, or "mcs")
-- probably due to morse code usage influence.
The pedantic argument back in the Olde Days was that a QSL card
confirming a QSO on "7180 kc" was wrong. (Just as "73s" on the
same QSL card was {and still is} "wrong".)

"7180 kc" is seven million one hundred and eighty thousand cycles.
Period. It could be 2 cycles today, 17 tomorrow, 6 the day after,
400 next week -- and, so on until the total number of cycles are
accumulated.

It's not until the "per Unit Of Time" is specified that we have
a _frequency_ .

(But, then, I think the QSL card should've stated
"41.783 Meter Wavelength".)

"K" means Kelvin (a unit of temperature), so "KHz" is incorrect, also. The correct form is "kHz."

Hi All,

As I've so freely wished for new services for Amateur use, such as RADAR, and by extension HAARP, events seem to be anticipating me, or at least my event horizon of imagination is growing. From the New York Times:

>A Bill Advancing Digital TV Is Approved by Senate Panel
>By STEPHEN LABATON

>had pressed the issue with members of Congress.
>
>A spokeswoman in the Washington office of Microsoft, Ginny Terzano,
>declined to provide details about Mr. Gates's conversations with lawmakers.
>She said the company was not seeking a provision for unlicensed spectrum
>use in the bill adopted on Thursday but generally favors such unlicensed spectrum.

What do I imagine? Amateur TV Broadcasting! Remember the ill-fated neighborhood FM? Interest groups sank that idea like a rock in the ocean. What does "Amateur" mean in this context? Discard the notion of transmitting only to exchange QSL cards and start pumping music and game shows produced at the community level. The prohibition against transmitting entertainment is a antediluvian appeal to the 1930s. "Amateur" in this context means non-commercial. Not even appeals for donations. Do it on your own or go back to vaudeville.

My notion to re-invigorate Amateur radio is to expand neighborhood TV transmission (small service area, AKA Pirate TV) making Hams the non-profit extension of the FCC for site review and inspection. Boost the technical requirements (sort of a low grade General Radiotelephone) for non-profit transmission testing and monitoring. Develop an association for granting area and frequency coverage (just like repeater associations have been doing for years) to co-ordinate allocations. There should even be provisions for networking.

A Hall effect device comes to mind. They're relatively inexpensive and should be available in surface mount technology. They are used in the automotive industry for things like engine rpm, throttle position etc. so the technology is robust. There would be a small amount of power consumption. The reed switch already mentioned is the simplest, draws no power when open but they are more prone to shock damage than a solid state device.

Reminds me of my very first trip to the United States back in 1972. I
was working at a computer company in Massachusetts, and while I was
there I gave a training course to a group of Texans from the US
airforce.

It took us nearly a week to get in sync, what with their Texurs drahl
an' my dulcet tones from the old British Empaah, don't y' know ... :-))

They were a great bunch of guys, though. Happy days!

The two well known amateur radio antenna manufacturers in the UK are Sandpiper and Moonraker. Both are small family owned and run businesses which make a reasonable product at a fair price for a specific market. I would not necessarily say that they are whiz-kids in antenna design theory - in fact I somehow doubt that they actually design them themselves (my sincere apologies to either/both if I am wrong) - but they both know what they are talking about from a construction and use standpoint.

I'm certainly sceptical of Moonraker, in both build quality and technical knowledge! I understand that sandpiper will actually construct custom antennas on a one-off basis, or in fact scale some of their range for different bands, I'm not sure if any other manufacturers will do that or not.

Saying that I've had no experience of sandpiper, although the GM3VLB mini-delta looks reasonable, and is not too expensive! I've had some minor things from Moonraker, and the build quality left something to be desired, but that is only a very limited experience of the company.

Hi RH, The proximity to ground, the ground type, and the length will
be the factors that determine the source impedance of the dipole. I
just ran a dipole cut for 21.3 Mhz by the formula, 18' up over real
ground and found it to be off by 3%. Moved it up to 36' and it was off
by 1%. Your 10% sounds a bit high. The conductor size of a wire
dipole will have some effect at 15m, but I did not try anything
different than #12 wire.

Just to be different, I tried #18 wire. Using 468/f gives a length of 21.9 feet at 21.3 MHz. According to EZneck, this is resonant at about 22 MHz. A length of 22.4 feet gave resonance at just a shade above 21.3 MHz. Making the wire 10% long put the resonance below 21 MHz. All at 18 feet.

I ran SWR from 21 to 22 MHz, with a step size of .05. Number of segments was 19.

Walter,

that brings back some old memories.

In the early 1960s I was, for a while, in the control tower at RCAF Greenwood Nova Scotia. Our ATC voice hotline linking several facitilites in the maritimes had a constant background of CW from NAA in Cutler, Maine.

A couple of years later I was stationed in Prince Edward Island where the local station, CJRW 1240, was about the same strength as a station in New Brunswick, CKCW 1220. In the background there always seemed to be a discernabile signal from NAA. I always assumed that this was due to the 20 kHz difference mixing with the 24 kHz of NAA and giving a very steady, but rather high pitched for CW, 4 kHz beat.

While in Greenwood it was also common to hear the Grennwood NDB (ZX) while in the car; since the beacon was on the IF commonly used in automobile radios in those days - 248 kHz? or something close.

The last one was really wierd. Some days when the weather was lousy we would hear an intermittent and badly distorted BBC signal on a VHF FM frequency. The technicians were convinced we were either crazy or drunk. Eventually it turned out to be a mixing problem involving two VHF frequencies and a BBC World Service station on the 15 MHz SWBC band. It only happened in bad weather because one of the mixing frequencies was the GCA (Ground Controlled Approach) frequency which was only really active in bad weather.

I don't reallyl think any of the above had anything to do with radials, but they triggered some long ago memories.

Hi Dave, that was probably because of the relatively short distance between
Cutler and Greenwood with respect to the VLF of NAA, along with its very high
power ground-wave signal. Incidentally, In the pre-war days of WW2 NAA was at
Arlngton, VA.

That's how I'd explain it, especially if there was non-linear substance deriving
a beat between the two BC stations.

2742. HIGH Q CAPS FOR VLF LOOP ANTENNA?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-23 04:00:44 UTC
From: TRABEM <>
Message-ID: <7l2ml1p4e9mjunf4ho30hd6uoj4e25756q@4ax.com>
Source record: 68339

What caps should I use for a resonant loop antenna for VLF? I have some antenna plans and need .2 uf total capacitance to resonate a loop antenna at 60 Khz.

I know I should avoid electrolytic and tantalum due to their poor temperature stability.

Disc ceramics are so poor thermally that they are out of the question, especially since the caps are going to be outdoors.

Silver Mica's are horribly expensive these days, and aren't available much past .01uf anyway.

I have a Mouser catalog and plan to order from them soon, but it's not clear which type of cap I should order.

Any suggestions for 50,000 pF caps that don't cost a fortune?

Note that this is a receive only antenna so voltage rating and current carrying capacity are not an issue.

Thanks.

T

==========
Avoid electrolytics and ceramics like the plague!

Since whatever you do, 90 percent of losses will be in the coil
resistance you have a good choice of capacitor types. Any type of
plastic film insulation will do fine. You may wish to have a 2000pF
air-spaced variable in parallel to cover a small frequency range.

0.2 uF = 10 times 0.02 uF. In any case you will need a number of
small value components in parallel for exact tuning of a high-Q
circuit.

The normal 5 or 10 percent tolerance means that you will have to
measure and select values from a larger batch of inexpensive

capacitors.

Don't forget you will have to select from a small number of standard values such as 0.22, 0.1, 0.047, 0.033, etc.

Specially manufactured close tolerance capacitors will cost the Earth.

Temperature coefficients don't matter very much but if you have a choice then select those with the lowest coefficient. But TC is seldom specified by manufacturers. You would need a very good capacitance bridge to measure the small TCs involved although it is easy to make TC measurements.

To reduce size of the capacitor just increase the number of coil turns. You will notice little or no difference in operation.

The most efficient loop has a single turn of very thick wire.
The ONLY reason for multiple coil turns at VLF is to avoid impractical values of capacitance. Receiving sensitivity does not depend on the number of turns, only on the area enclosed by the loop.

A change in the number of coil turns involves only a change in how the loop is Z-matched to the receiver. With a single-turn coupling loop no changes are needed.

You may find program RJELOOP3 useful. It covers multi-turn square loops and other regular shapes of the same enclosed area.

Download program from website below in a few seconds and run immediately.

This is a bit off topic but I was wondering if anyone knows where
I could find a selection guide for through-hole, small signal RF
Transistors.

I have been using SMD but want to purchase some VHF and UHF transistors
for prototyping. The suppliers have a list of parts available by part
number but no description and is is taken forever to search each part
number to see if it is suitable.

Thanks in advance

Regards
David

2745. The Evolution of Boy Scout Headquarters Station K2BSA

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-23 15:11:58 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <bf8nl1hggrtl3iqviff3jli9asj90h93f4@4ax.com>
Source record: 68342

The Evolution of Boy Scout Headquarters Station K2BSA

It's very likely that you've either heard, or heard of K2BSA, the club station at the National Headquarters of the Boy Scouts of America, located in Dallas, Texas. Then it's also likely that you'd be interested in learning a little background on how the station originated.

It is well known that in 1910, Britisher Lord Baden-Powell founded the Boy Scout movement in England. The movement soon caught on in the US, with its original Headquarters located at 2 Park Avenue, New York City until the early 1960's. After WW2, three top executives at Boy Scout Headquarters were radio amateurs who desperately wanted to have a Boy Scout Headquarters'club station, but there was no room in the crowded office complex for such a frill. These amateurs were Lloyd Everhart, K2CVT, publisher of all Boy Scout publications, the late Harry Harchar, W2GND, editor of Boys' Life, and E.E. 'Hoisy' Hoisington, K2GDR (now W4YTA), Chairman of the Safety and Health Department.

Around 1960 these amateurs came upon some exciting news. Due to the increasingly cramped office space, a move from New York was essential. To make the move possible Headquarters had just acquired some pristine wooded acreage in North Brunswick, NJ, at the intersection of US 1 and US 130, just south of New Brunswick, the location of station WII with its 200 kw Alexanderson alternator transmitter operating on 21.8 kHz. This was the station used to transmit President Wilson's ultimatum to Germany that resulted in the ending of WW1.

Our three amateurs descended onto the property with glee, because in addition to a long nature trail and large office complex building housing the Headquarters' business operations, a large, magnificent museum was built to display Boy Scouting memorabilia from all over the World. Their immediate thought was, "What neat place to operate and display ham radio!" The main display room was about the size of a standard basketball court. At one end of the room an attractive console was constructed in clear maple for the long desired amateur station.

Various manufacturers of amateur gear generously donated equipment to the station. Hallicrafters were the first, donating an HT?-111 transceiver, and an HT-37 RF power amplifier. The late Al Khan, K4FW, (then with Electro-Voice and owner of Ten-Tec) donated an EV-664 microphone, and Telrex donated a tower and its then top-of-the-line three-band beam and rotator. Later on, Hammarlund donated their latest transceiver, and then still later, Heathkit donated an SB-101 transceiver and an SB-200 RF power amplifier.

It was my good fortune to live in Dayton (800 miles east of the Hara Hamvention Dayton), only eight miles south of the new Headquarters on US 130. By sheer coincidence Hoisy, K2GDR, moved in just down the street from me, and naturally, both being hams, we became good friends. What was even more fortunate for me was that he invited me to join with him, Lloyd, and Harry to assemble the station. Guess what? Among other tasks, they gave me the responsibility for the antennas! What joy that task was. We four then formed the 'Boys' Life Radio

Club' and the original call assigned to the new station was K2BFW, which will be featured in an interesting story later on.
The station operation was very successful. Not only did we four of the Club enjoy operating the station, but all scouts and scouters visiting the museum, who were also licensed amateurs, and other visitors who were licensed, were given the opportunity to operate the station in the same manner as those who visit W1AW at the ARRL Headquarters.
But as luck(?) would have it, the K2BFW operations seemed to go awry during the week-ends of JOTA, the yearly October World-Wide Jamboree on the Air. This was the time when we expected to have an exciting bit of operation with the new station, when Boy and Girl Scouts visit nearby amateur stations to talk with other Boy and Girl Scouts over amateur radio. And every year, we at Headquarters had licensed scouts and scouters lined up for twenty-four hour operation of K2BFW throughout the entire JOTA weekends.
But alas, a distressing problem arose during JOTA--every year. A scoutmaster, a licensed amateur in Pennsylvania right across the Delaware River from us, obtained a special event call sign for the JOTA--K3BSA! Wow, the pile ups he drew! Everybody thought he was the Headquarters station. 'Ol K2BFW was left in his dust, and when we announced during every contact that we were the Headquarters station, many of our contacts disbelieved us, and told us to get off Headquarters' frequency. However, we still made many successful contacts, including lots of DX. We were always able to work HB9S, World Scouting Headquarters, in Geneva, Switzerland, where some of our own Scouting executives had the opportunity to talk with their counterparts in Geneva.
After several years of the distressing problem emanating from K3BSA I decided we needed more recognition and visibility than we could possibly get with the call sign K2BFW. So I decided to get us a new call sign that would give us the clout we needed. On checking the Call Book it was obvious that both W2BSA and K2BSA were in use. Well, it was also obvious that W2BS wasn't in use-but better than nothing,
As a former monitoring officer with the Radio Intelligence Division of the FCC I was personally acquainted with Rosel H. Hyde, then Chairman of the FCC. I told him of the situation and asked his advice on how to proceed in obtaining a permanent assignment of the call sign W2BS to the Boy Scout Headquarters station. He suggested that I present the situation in the form of a draft petition that he would take to the Chief of the Safety and Special Services Bureau for his comments. (At that time, the Amateur Division fell under this Bureau's jurisdiction.) Chairman Hyde was in complete agreement with our request. However, the Bureau Chief rejected the petition, saying there were no administrative rules allowing a special call sign to be assigne permanently in cases such as ours. In addition, he stated that old timers who already had two-letter calls would object to a Boy Scout station having a two-letter call. This last comment in his response seemed to me to be a lame excuse.
After learning of this response Chairman Hyde suggested that I revise the petition to include some means for overcoming the Bureau Chief's objections. He also advised me to submit the revised petition directly to the seven FCC Commissioners.
I then started some research. I pored over old Call Books between 1921 and 1928, and to my surprise I found more than 50 two-letter calls assigned to Boy Scout troops all over the Country. (I also discovered the early FRC policy of

assigning two-letter call signs to universities and colleges, all with suffixes beginning with 'y'.)
The revised petition included a report on my findings concerning the two-letter calls assigned to Boy Scout troops in those early days. By this time Chairman Hyde's tenure had expired, and was replaced by Chairman Dean Burch. However, Chairman Hyde remained as my advisor, and heartily approved of the revised petition.
As Chairman Hyde had advised earlier, this time I submitted the new petition directly to the FCC Commissioners on April 16, 1971, One of the arguments in the new petition for a permanent assignment of a call sign for the Headquarters' station I thought would help our position was that in addition of its use at Headquarters, the call could also be used by other scouting groups for their activities in all parts of the Country, simply by obtaining permission from the current trustee of K2BSA, and applying the appropriate /n for the District in which the operation occurs. This aspect of the permanent call sign would then relieve the FCC staff from the paper work required to process special-event call signs for other official Scouting activities, such as Jamborees. (I later took some lumps from the FCC staff on this issue, because some Jamboree leaders later ignored that aspect of the petition and requested special call signs WJ7WSC for World Scouting C?
However, after the usual long wait for bureaucratic action, on April 1, 1969, I received a letter directly from the Chairman of the FCC himself, Dean Burch, saying the Commission found that they believed the call sign K2BSA would give Boy Scout Headquarters the recognition and prestige required to let the amateur community know who we were every time we went on the air. Petition request granted!
It seems that during the time I was doing the research, the call sign K2BSA had become inactive, and was therefore available. K2BSA was thus assigned to our club station of the Boy Scouts of America Headquarters! As word got around concerning the new call sign, our local scouts and scouters started increasing our visibility by putting in more time on the air, and the positive responses we received proved that our recognition as Scouting National Headquarters was also increasing dramatically.
During the first years of operation with the call sign K2BFW, Harry Harchar was trustee of the station, but from the time of the new call sign until Headquarters moved to Dallas, I was the trustee, and also the National JOTA coordinator. As JOTA coordinator I was principally a PR man, publishing the pertinent operating information in the October issues of the various amateur publications, including QST, Ham Radio, CQ, and 73.
However, all did not bode well for the Headquarters' move from New York to New Jersey. It appears that Scouting organizations in the Western portion of the Country felt that the new location should have been more centrally located between East and West to provide a more equalized service to the West. The situation simmered until the 1990's, when the tough decision was made to move to Dallas. For the operation of K2BSA it was not only a tough call, but a fatal one--but fortunately, only temporarily.
Alas, a firm, unbendable high-level Headquarters decision was made that there would be no amateur operation and no antennas erected at the new building in Dallas. PRB-1? Then only in an amateur's dream. What then should become of the present equipment? It was decided to distribute it among the four of us,

Lloyd, Harry, Hoisy and myself. As an affcionado of early equipment it was my good fortune to inherit the original Hallicrafters 111 transceiver and the HT-37 power amplifier, which I still have in my collection.
Fortunately, quite some time after the move to Dallas, a Dallas Scouter who was also an ardent amateur, and then the SCM for the North Texas ARRL District, the late Walter 'Dan' Dansby, Jr.,W5URI, considered it untenable that K2BSA operation was killed simply by bureaucratic executive order. Dan then started a search for a suitable location to house K2BSA and get it back into operation. He initially found a place to house the station at Camp Shuman on Lake Worth near Azle, Texas, and later moved to its permanent home at Camp Wisdom in Dallas. The station's trustee is Ray Moyer, WD8JKV, and the station manager is Frank Krizan, KR1ZAN. K2BSA's equipment consists of two HF operating positions, a VHF/UHF satellite position, VHF/UHF voice and packet position and amateur TV (ATV) operating position. The station is operated during Jamboree on the Air (JOTA) and several other weekends of the year. Maintenance is done by Crew 73 members and Advisors of Richardson, TX.
Since September, 2000, K2BSA has been operating, and open certain Saturdays of each month for visiting Scout groups to tour and talk with other Hams and, perhaps, other Scouts around town, around the country and, often, the world. Watch the K2BSA web site for details or call the Circle Ten Council reservations desk 214-902-6764 (beginning in July 2000) to schedule a visit. Finally, it is comforting to know that through the operation of K2BSA, Amateur Radio is being kept alive within the Boy Scout movement, giving its youth an introduction to our hobby and service, and hopefully instilling a desire for them to become a part of our great Amateur Radio Community.

vinegar and salt should make quick work of it... neutralize with baking soda
or just rinse really well. don't leave them overnight or you won't have any
wire left, just rub it in and wipe off the crud.

You didn't say how many strands.

If it is 7 strand, you may be able to unlay the strands and scrape the
oxide off with a knife, or polish it off with some stainless steel
wool or the like (dont soak it in steel wool overnight!).

"Common household products" excludes weak muriatic acid solution, and
acid flux, doesn't it, so I won't discuss them. If you do find a
common household acid that works, remember the risk of residual
contamination of the strands, and also, wicking up into the insulated
part if it is insulated.

One of the advantages of single strand bare antenna conductors is that
they are easier to clean, and you can even use acid cleaners without
risk of residual contamination of the strands and wicking up into the
insulated part.

Outright replacement might be the best option.

Damn! I've been hamming for over 40 years, yet I've never tried
that. I have a need to clean up and re-use some 7 strand copperweld
antenna line so I ran out and just tried this on a fairly corroded end.

It worked super well, and cleaned up each strand, actually getting
down around each strand pretty well even though I didn't spread them.

Thanks for reminding me of this old tip.

yeah, sometimes us young whippersnappers can teach you old fogies a thing or two! i've only been at this for 27 years. i learned that one to clean copper bottom pots. as someone else pointed out, be sure to neutralize it with baking soda or at least rinse off really well, especially on stranded and insulated wire. if the vinegar stays down between the strands it can cause more corrosion.

In the late 50s, Al Kahn (W8DUS president of ElectoVoice) and I ran the amateur radio station at the Jamboree at Valley Forge. I no longer remember the call sign used. Al went on to found TenTec and passed away within the year. I went on to Ohio State, mentoring by W8JK, and teaching.

Al was a great person. He let me drive his Thunderbird (then a sports car) into town to get some parts. Exciting! He also taught me some valuable lessons.

Wish that I could remember the call sign that we used.

Thanks Walt for putting down the story that I have heard you tell before. I am an Eagle scout and it is especially disappointing not to have more of an amateur radio presence in Scouting.

Polystyrene caps are very temperature stable, typically changing only 0.5%
over their full temp range. And they're available in high capacitance
values. Check Mouser and Digikey for good prices.

>

I've ordered a good supply of polystyrene caps in the standard values.
I also have an RCL meter, which is cheap and not accurate, but I can
measure the actual value of the caps I get from Mouser and assemble
them to hit the target frequency pretty easily. So, I'm actually
hoping the values they send are somewhat dispersed from the marked
values.

>Specially manufactured close tolerance capacitors will cost the Earth.

>specified by manufacturers. You would need a very good capacitance
>bridge to measure the small TCs involved although it is easy to make
>TC measurements.

I learned about TC in the WB4VVF Accukeyer days when I was much
younger and foolish. I built one, it worked great. But, I used a disc
ceramic cap for the clock speed generator. I could actually detect the
keyer changing speed as I sent cw, which I assumed was due to the TC
of the disc ceramic. Touching a soldering iron to the outside of the
cap drove the keyer speed wild. Anyway, I learned my lesson about
disk ceramic caps the hard way and didn't want to repeat the error 25
years later by using a cap that didn't have a good temco.

>
>To reduce size of the capacitor just increase the number of coil

>
>The most efficient loop has a single turn of very thick wire.

Which is exactly what I intend to do! I had a choice between large
copper welding cable and 3 inch copper pipe. I chose the welding cable
because it was actually cheaper although I'm not sure which would have

the best Q.

>The ONLY reason for multiple coil turns at VLF is to avoid impractical
>values of capacitance. Receiving sensitivity does not depend on the
>number of turns, only on the area enclosed by the loop.
>
>A change in the number of coil turns involves only a change in how the

>no changes are needed.
>

Actually, I have a receiver with a 2 ohm input impedance Reg. So, it can be fed directly from the series tuned loop. My only selectivity in the front end of the receiver will be the loop tuning, so Q is important.

The receiver is small and draws low power, so I am going to locate the receiver at the antenna and feed the audio to teh house with common mode audio transformers...thus avoiding the chance to conduct household noise from the house to the receiver through the connecting cable.

>You may find program RJELOOP3 useful. It covers multi-turn square

>immediately.

Already got RJELOOP3 and love it Reg. It has helped immensely and saved me so much time because it allows me to evaluate how good antennas will work without having to assemble them! Thanks for making the software available.

>

I use a product called CLR. It is used to remove calcium, lime and
rust from bathroom fixtures. The stuff I use (in the bathroom and on
the wires) comes in a green plastic squeeze bottle. It reduces
(chemistry context) the oxide and leaves the copper bright and shiney
and ready for the solder. I use flux, silver solder and a torch when
I solder SMT components (just kidding!) antenna wires. The flux gives
a better joint and the silver solder seems to be stronger although
your mechanical strength should come from the Western Union twist you
put in the wire. I squirt the stuff into a ceramic bowl and use a
cheap brass bristle brush to clean. Rinse well with water.

Most capacitors are rated at the same frequency that most RCL meters
(for good reason) run at: 1KHz. This is not to say capacitance is the
same at 60KHz. It would be simpler to build your antenna with a
tickler coil in an oscillator circuit and measure the resonance
frequency.

>So, I'm actually hoping the values they send are somewhat
>dispersed from the marked values.

They usually are, but are also within the stated error band. That is
to say if they are spec'd at ï¿½5% you might them spread from +1% to
+5% of nominal rather than across the full range of -5% to +5%. The
upside is tighter matching, the downside is no offsetting average
centered around nominal.

>>To reduce size of the capacitor just increase the number of coil
>>turns. You will notice little or no difference in operation.

>because it was actually cheaper although I'm not sure which would have
>the best Q.

And this is where most of the advice so far (and the perception of the problem) comes into a clash with reality. I will quote from your earlier post to make the point:

>>>Note that this is a receive only antenna so voltage rating and current
>>>carrying capacity are not an issue.

Current carrying capacity is an issue, that is why it is called Q!

Simply having smaller currents does not boost the Q of these pitifully meager leads on the capacitors going to the comparatively garganthuan copper pipe. Even more, and especially at this frequency, contact resistance of the plates of the capacitor to the leads is an issue that has been studied and resolved for designers of switching power supplies (which typically run in this frequency neighborhood).

What you need to research for are caps with low ESR (Equivalent Series Resistance), or test your selections along the lines offered at: http://octopus.freeyellow.com/99.html

This returns us to the discussion of Q (we never really left), but for capacitors is measured as DF (dissipation factor, something that is generally ignored for transmission lines because the loaded Q is so very low - as Dorothy would offer "Toto, we're not in Kansas anymore!"). You could be killed by ESR and not know what hit you.

The suggestion for Polystyrene may be good, but only for a particular manufacturer or for a particular run. It requires individual examination and specification, especially when you've been warned away from ceramics which can exhibit ï¿½15ppm/ï¿½C (how good do you want it?). The real trick is to simply accept you are going to get some that drift and plan to offset that drift with another parallel formula that drifts in the opposite direction such as: polyester and polypropylene, or polystyrene and polycarbonate.

Hey those tiny square blue bypass caps are great for measuring
temperature. I had one on the workbench in a bridge and the IR heat
from my bare hand was changing the reading from at least a foot away!
Ceramic bypass types vary their capacitance a lot with temperature and
voltage.

Source record: 68360

Caps to consider: as you've already figured, polypropylenes can do very well. Mylars/polyesters are not very stable, and don't have as high a Q as polyprops. They also show greater distortion, which may or may not be an issue to you. C0G ceramics should work fine. Be aware that the loop inductance will change with temperature, too, as the loop size changes. Presumably your loaded Q won't be so high that it's a problem: 50ppm/C over 20C is 0.1%, which wouldn't be noticable, most likely, with a loaded Q of up to 500 or so. At 60kHz, Q=600 is only about a 100Hz bandwidth, so I suppose you won't want a higher Q than that anyway (assuming you could get it). I'm curious: what loaded Q do YOU expect to get? How big is your loop going to be? What impedance do you expect with the loop resonated?

Cheers,
Tom

Richard,

I'm a little surprised you have time to spy on my activities. I trust you are not a spare-time member of the CIA which appears to take an interest in most things which go on on this planet. By the way, your use of the English Language has recently improved. I have been able to understand better what you are talking about.

But your concern about Effective Series Resistance (ESR) of the tuning capacitors in connection with VLF tuned loops is a bit overdone. Remembering Lord Kelvin, let's crudely quantify things.

All we have to go on is Trabem's value of the tuning capacitor of 0.2 uF.

Therefore the size of his loop is a square of sides = 5 metres. Total length of wire = 20 metres. Or somehing similar.

Assume the wire diameter is a conservative thick 2mm.

Therefore we have L = 31 microHenrys, Reactance at 60 KHz = 12 ohms, and RF resistance 0.23 ohms.

From which the intrinsic Q of the loop inductance = 50.

Assume the tuning capacitor is comprised of ten 0.02 uF capacitors in parallel. The resistance of 10 capacitor leads in parallel is negligible in comparison with the loop's single-turn conductor RF resistance of 0.23 ohms.

He, Trabem, will be obliged to use a bundle of capacitors to make an EXACT value for the tuning capacitor because of the impossibiltity of obtaining a single capacitor of exactly the correct value, at a particular temerature, and of sufficient long-term stability. He can't afford it!

Immediately, the ESR of a 0.02 uF capacitor, whatever it is, is divided by 10. Yes, I know that the ESR of a capacitor at 60 KHz involves a little more than lead resistance. But it's too small for an American General Radio bridge to accurately measure it.

But to return to Earth, the working Q of the 5-metre-per-side loop is a function of the sum of the conductor resistance, plus the small ESR, plus the radiation resistance (which is also negligible), PLUS the

loss resistance due interaction of the loop with its environment.

Unless the loop is removed from ground and other foreign structures by at least 1/3 of its diameter the losses due to its environment will greatly exeed all other losses.

If the environmental loss is equal only to conductor resistance loss, the working Q of the loop will be reduced to 25.

With a Q of 25 the bandwidth will be of the order of 60/25 = 2.4 KHz, or enough to accommodate an audio SSB transmission.

And getting down to practicalities, this means that the 0.2 uF tuning capacitor has to be adjusted to an accuracy of about 0.3 percent, or within a few hundred pF.

That is why I suggested a 2000 pF variable capacitor be included in the bunch. A 2000 pF variable capacitor consists of an old fashioned 4-gang, 500 pF, receiving-type capacitor with all sections connected in parallel.

As the loop is to be installed outdoors (with 5 metre sides it HAS to be) the variable 2000 pF component might be useful to re-tuning it between summer and winter temperature variations.

It's surprising what can be gleaned from a knowledge only of the value of the proposed tuning capacitor.

Its all guesswork of course.

Incidentally, if Trabem obtains batchea of nominally identical value capacitors, he will probably find they are all on the same side of the tolerance. They probably all came from the same production line and machine settings. Production values are not distributed at random. This can seriously handicap his choice of particalar values to make up the total of 0.2 uF.

Regards, Reg, G4FGQ.

Too bad it's not an IC-745 which has an analog voltage output
proportional to the pre-WARC ham bands.

I designed such a device about ten years ago. It works on any
100 watt transmitter. It had a divide by 1024 pre-scalar to
bring the signals down to a comfortable speed for CMOS logic.
Then a window would open for ~4mS and a 2048 max counter would
record the counts. Those bits were stored and used as address
bits on an EPROM whose output indicated the band. I used it to
automatically switch in variable lengths of ladder-line depending
upon the band.

I wonder how many people would be interested in me digging
up that old design which is buried in a box in my garage?

Hi Reggie,

There is no room for surprise and even less interest in your
"activities" whatever that term means. As for the time to accomplish
such a simple act - that is eclipsed in simply responding with these
first two sentences.

>But your concern about Effective Series Resistance (ESR) of the tuning
>capacitors in connection with VLF tuned loops is a bit overdone.

Clearly you in over your head, Old Son. I would suggest you exercise
your own skills in spying out common literature on the subject.

>Remembering Lord Kelvin, let's crudely quantify things.

Sure, this exercise is going to floor you because you are clearly
quantifying only those things you are aware of. ESR is clearly beyond
your experience horizon given the howlers of dismissal you offer.

>All we have to go on is Trabem's value of the tuning capacitor of 0.2
>uF.
>
>Therefore the size of his loop is a square of sides = 5 metres. Total
>length of wire = 20 metres. Or somehing similar.

We have a loop so small, by your own reckoning, that its Radiation
Resistance amounts to barely 20 nanoOhms. This is not outside of the
realm of a simple reckoning - Lord Kelvinator would roll his eyes at
such omissions. The same efficiency issues that plague driving this
as a transmission antenna also plague it as a receiving antenna. I
see you neglect your own Kelvinator assessment of efficiency in your
cavalier dismissal.

>Assume the wire diameter is a conservative thick 2mm.

In the face of a stated choice of:
>>I had a choice between large copper welding cable and
>>3 inch copper pipe. I chose the welding cable

>Therefore we have L = 31 microHenrys, Reactance at 60 KHz = 12 ohms,
>and RF resistance 0.23 ohms.

Adding loss seems to serve the argument rather than the plan.

>From which the intrinsic Q of the loop inductance = 50.

Lord Kelvinator would throw his chalk at you for such reliance on what
is so easily measurable instead of being conjectured.

>Assume the tuning capacitor is comprised of ten 0.02 uF capacitors in
>parallel.

This is another failure that Lord Kelvinator would dope slap you with.
WHAT capacitors? What materials are being used, what vendor? what
specification? You are egregiously deficient in the particular of
MEASURABLES and you simply skip the SWAG. Is this the Kelvinator
ethic at work? This is lower 4th form effort. You are simply arguing
what you are familiar with and what follows reveals a vast
intellectual hole:
>the ESR of a 0.02 uF capacitor, whatever it is, is
>divided by 10. Yes, I know that the ESR of a capacitor at 60 KHz
>involves a little more than lead resistance. But it's too small for an
>American General Radio bridge to accurately measure it.

You clearly left the bench before the General Radio 1650-B became
commonly available to the calibration labs 40 years ago. There is
also the ESI Electro Scientific Inc. 250 DA Impedance Bridge. Both
bridges span 6 orders of magnitude for D measurement. We can presume
you have no experience with the Hewlett Packard HP 4270A either.

Going further (and certainly more modern) we have the ANDEEN-HAGERLING
AH 2700A which offers loss down to a dissipation factor of 1.5x10-8
tan d. This, by the way, does not extend above 20KHz but certainly
blows away any argument of anything being too small for its 12 ORDERS
of magnitude to encompass.

I could offer more examples, but that would be like shooting fish in a
barrel.

Reggie, you are simply gusting on with confirmed bafflegab:
>Its all guesswork of course.

>Incidentally, if Trabem obtains batchea of nominally identical value
>capacitors, he will probably find they are all on the same side of the
>tolerance.
Let's see, I said that already and you parrot it either
1. without attribution (plagiarizing);
2. responding without reading;
3. both.

The 706 (on pin 5 of the 13 pin accessory socket) still has the Icom analog voltage output based on the selected band BUT unfortunately it is not a unique decoding. From some notes of mine it looks like:
160m = 7.0-8.0V
80-75m = 6.0-6.8V
40m = 5.0-5.8V
30m = 0V
20m = 4.0-4.8V
17m-15m = 3.0-3.8V
12m-10m = 2.0-2.8V
6m-2m = 1.0-1.9V
When I realized that 17m and 15m decode the same and 12m and 10m decode the same I dropped the project. However this may not concern you. The best way is to decode the CIV bus and read the frequency on the bus but this is more complicated.

After 47 years of hamming, I found that this is the best way to clean corroded stranded #14 copper antenna wire (may also work on #12) especially if you experience another "Rita"

1.) Make yourself a strong MargaRITA drink using ONLY Hornitos Tequilla.
2.) After you finish drinking the MargaRITA, dip the end of your antenna wire into the residue at the bottom of the glass.
3.) Using the lemon slice, carefully wipe the end of your antenna wire clean.
4.) Repeat 1 through 3 four times.

And there you have it. Reconnect your antenna and go work some real dx for a change and enjoy your lowest noise level you have ever experienced.

Note: If you are trying to clean off some ladder line, just use a wider glass.

It worked for me over the years and I am sure it will work for you.

The idea of having to use identical values of caps is a bit off track. You build the capacitor bank up with obtainable value units, but add smaller values (it's called trimming) to get to the exact capacitance you need. I saw a VLF loop antenna that used such an arrangement, and as the fine tuning element, there was a couple varicaps in parallel. There was also a thermistor that fed temperature data back to an opamp circuit that controlled the bias on the varicaps. The end result was an antenna that was very well compensated for temperature. The loop stayed tuned within a few hertz of it's tuned frequency over temperatures ranging from around 0F to over 100F. The antenna was part of a VLF frequency calibration system. Can't remember the make/model... it was a number of years ago. Tracor seems to ring a bell, but not sure.

Assume nothing Reg.

The loop is indeed 5M per side.

But, it is however made out or 2/0 copper cable used for arc welding.

I got a good deal on it. It has many many fine strands, never bothered
to count them or to measure the diameter of the individual strands.

But, suffice it to say that it is much larger than 2 mm.

I'm hoping for a Q of 600 at 60 Khz.

I looked at 3 inch copper pipe, couldn't estimate which had the better
ac resistance, so I went with the welding cable rather than the large
copper pipe.

I have some 365 pF air variables I planned to use one for fine tuning
the loop.

There will be no ssb reception. Generally I'm interested in 6 to 10 Hz
wide channels at 185.3 Khz and in the 137 KHz ham band.

Fortunately, I have a DDS with a tcxo, so I can spot the frequencies I
want to listen on and then tweek the loop with the variable cap.

>about a 100Hz bandwidth, so I suppose you won't want a higher Q than
>that anyway (assuming you could get it). I'm curious: what loaded Q
>do YOU expect to get?

> How big is your loop going to be?

Around 5.2 Meters per side.

> What
>impedance do you expect with the loop resonated?

It should be under 1 ohm. I don't exactly know the ac resistance or
how the Q of the C and the Q of the inductor combine.

My loop material is 2/0 copper welding cable, many fine starnds. I
considered 3 inch copper pipe, but couldn't get an estimate of the ac
resistance for either, so I chose the copper cable.

I'm puzzled. My copy of rjeloop3 suggests the Q will be about 200 at 60kHz with a 9mm wire diameter, and you'll see about 2kohms when it's resonated. Are you not taking the output across the ends of the loop (across the capacitor)? And with a skin depth of about 0.01" at 60kHz in copper, certainly 3" diameter soft copper pipe would have the lower resistance. You might have some trouble finding soft copper pipe, though. But even hard copper pipe should have a low RF resistance. "Reference Data for Radio Engineers" (or "Reference Data for Engineers" in newer incarnations) has lots of good info for figuring out things like RF resistance of copper wire. I assume your welding cable doesn't have strands that are insulated from each other like Litz wire.

Consider that Q is energy stored divided by energy dissipated per radian (1/2pi of a cycle). Then the net Q will be 1/(1/Q(inductor) + 1/Q(capacitor)). So if the cap and inductor have the same Q, the net Q will be half that. And if you put a resistive load across the coil+cap, that will dissipate power and lower the Q further.

Cheers,
Tom

In all likelihood you won't be able to tell the difference. A 1:1 SWR at 75 Ohms still leads to the radio thinking the SWR is 1.5,and the radio will be seeing 75 Ohms at resonance. If you use 50 Ohm coax, the SWR will be theoretically 1.5:1, but the actual impedance can be anywhere on the 1.5 circle of the Smith chart, depending on the length of the coax. Probably, using 75 Ohm line would be more "proper". You probably know that you can make the dipole impedance 50 Ohms by making the center higher, and drooping down the ends. I just wouldn't let the ends go any lower than the 18 feet that you have.

Source record: 68377

Stranded, layer-wound wire, even when strands are individually
insulated, behaves similar to solid wire of slightly smaller diameter.

The strands in true Litz are WOVEN such that every strand spends the
same length in inside and outside and intermediate layers of the
cable.

Current is then more uniformly distributed throughout the conductor's
cross-section.

The diameter of an individal strand should not be greater than about
about twice skin depth. Otherwise effectiveness decreases. Thus, at
high frequences where skin depth is very small, very fine wire must be
used.

There are practical and economic limits to the fineness of drawn
copper wire. There is little to be gained by using ordinary Litz
above 3 or 4 MHz. At high frequencies with small coils of few turns,
such as receiving coils, tank and loading coils, it is far more
economic to increase Q just by increasing the diameter of solid copper
wire. Litz is at its best from VLF to IF and MF.

Another set of questions: Given the high atmospheric noise level at LF/VLF, is there really a need for such a large loop as you propose, for receiving? How quiet is your receiver front end? In other words, will such a large loop significantly improve your SNR on weak signals? Do you have a reason other than signal level for using such a large loop? What about the response to nearby strong electric-field noise generators of a large loop versus a smaller one?

Cheers,
Tom

There are some commonly occurring lengths for multi-band dipoles. I see 105', 135', and 140'. Is 140' preferred over 135'? If so, what is the benefit of going from 135' to 140'? Just curious.

That's about a 3.5% difference. You get just about that much difference
between insulated and uninsulated wire. That much difference in length
doesn't much matter for non-resonant length dipoles. However, for
resonant dipoles, length certainly matters and 140 ft. would probably
be resonant outside of the 80m band. For instance, a resonant 1/2WL
dipole for 3.8 MHz would be about 123 foot long.

Hi RB, With multi-band dipoles you will have to use an antenna tuner. The lengths you see in the charts are chosen such that the antenna+feedline will have an impedance (hopefully) on multiple bands that your antenna tuner can handle. Usually if a 135' dipole won't load on a certain band, the feedline length is changed, because it is easier than bringing down the dipole and changing to 140'.

You are absolutely right about the size of the loop.

A larger loop might not enhance the ability to copy a weaker signal. And, I spent a small fortune in buying big wire just to make it have a reasonably high Q. My question about the caps was merely to make sure that I was buying the right type of caps, so that the investment in the larger sized wire didn't get negated by having the wrong type of cap.

At some time I might like to evaluate a smaller loop against the big one in terms of the actual weak signal reception capability.

The receiver is hot on HF and should be just as good on LF and VLF.

Ultimately I'd like a shielded loop, but the effect of the stray capacitance seems to really kill the Q. The shielded loop camp makes a convincing argument in that the magnetic field is significantly quieter than the electrical field is. But, how to do a shielded loop without knocking the Q all to Hell is a significant issue. Needless to say the potential for interference by strong LF broadcasters is much reduced by shielding the loop as well.

One user I spoke to recently commented on the quality of reception with his shielded loop.....signals that were buried in noise by quite a few db seem to pop up into Q5 readability when the shielded loop antenna is switched in. So, I know they work. Just not sure how to implement them without incurring a lot of loss in Q from the stray capacitance introduced by the shielding.

==========

To calculate change in velocity due to plastic PVC insulation we need
to know :-

Wire diameter = d
Diameter over insulation = D
Height of wire above ground = H
Permittivity of insulating material = K

First calculate capacitance of bare wire to ground.
Then calculate capacitance of insulated wire to ground.
Velocity Factor = SquareRoot of their ratio.
Neither Terman's nor Kraus' Bibles will mention the following
formulae. So you'll just have to take my word for it.

Velocity Factor = SquareRoot((A + B) / C)

Where -

A = K * Ln(4 * H / D)

B = Ln(D / d)

C = K * Ln(4 * H / d)

Example :
Bare wire diameter = 1.6 mm = 14 awg.
Diameter over insulation = 2.6 mm.
Height above ground = 10 metres = 33 feet.
Permittivity of insulation = 3.5

Velocity factor = 0.983
Or a decrease in resonant frequency of 1.7 percent which can nearly
always be forgotten about.

The electrical effect of the enamel on magnet wire is entirely
negligible. But it does protect the wire from atmospheric pollution.

You need first to realize that the "shield" IS the antenna. The whole point of the "shielded loop" is that you can make it very symmetrical, which is just what's needed to reject strong local electrical fields. The symmetry does nothing to reject electromagnetic signals. BUT you can make an "unshielded" loop which is as symmetrical as a "shielded", if you are careful, and get the same advantages. If you really want to build one like a classical "shielded loop" and maintain high Q, just build the "shield" out of copper pipe and put the capacitor across the gap. The wire inside the pipe is just the center conductor of a short piece of coax connected to the feedpoint.

If you don't understand this, please see King, Mimno and Wing's "Transmission Lines, Antennas and Waveguides." It's explained quite nicely in the "antennas": chapter. It's also explained reasonably well in Johnson and Jasik's "Antenna Engineering Handbook."

Read the following:
http://members.dslextreme.com/users/w6wqc/antenna.html
The data on antenna efficiency is a misinterpretation of the NEC output
file. It refers only to copper losses, and does not include ground losses.
The discussion that "The length of an antenna wire is irrelevant" is the key
point made.

73,

Frank

Hi Tom,

No, I don't understand this. I thought a shielded loop meant the loop antenna wire was shielded by the copper (non-ferrous) surrounding the wire. The shield tends to protect the wire from electrical field inputs and allows it to only respond to magnetic field variations.

I thought the capacitance between the wire and the surrounding shield material represented a loss in Q, therefore a loss in output voltage. So, a loop that might have a Q of 100 in free space would have a much lower Q if the loop wire was enclosed in a non-ferrous pipe.

There are countless horror stories about those attempting to use surplus hardline as shielded loops on LF and VLF, all with disappointing results. The predominate attitude was that the capacitive coupling between the wire and the shielding material was the cause. I don't say the predominate attitude is correct.but, if it is a false assumption, then I am not the only one who needs revision:))

If the copper pipe IS the antenna, then why have the wire inside it at all??

I must say I'm more confused now than I was before reading your message.

I'm sorry, I have to leave now. The director of the asylum is calling.....

It is not an effective antenna shield if it is wholly continuous - and it is not, it has a gap opposite the mounting point which is generally at ground/reference potential. Part of the point of being "shielded" is to enforce a symmetry and that ground/reference is electrically neutral as long as you guarantee it is equidistant both sides around the loop to that gap.

> The shield tends to protect the wire from electrical field
>inputs and allows it to only respond to magnetic field variations.

There is no such thing as "only" magnetic fields variations.

>I thought the capacitance between the wire and the surrounding shield
>material represented a loss in Q,

Q is a simple relation between loss and storage. Lower Q for the same storage (be it in a capacitor or an inductor) can only result from resistive loss of Ohmic conduction or radiation. Any loss attributable to a capacitor is conductive loss - hence the discussion of ESR. You would have to go back to the stone age of electronics with paper and wax dielectrics to find loss BETWEEN the plates. Equivalent Series Resistance for garden variety capacitors, when compared to radiation resistance, is not trivial. That is, unless, you swamp that loss by putting your loop in the closet with your mothballed summer wardrobe or burying it in the garden mud. Design for failure is easily achieved if you need a rationale to ignore simple considerations.

Consult:
http://www.w8ji.com/magnetic_receiving_loops.htm

>There are countless horror stories about those attempting to use
>surplus hardline as shielded loops on LF and VLF, all with
>disappointing results.

Such disasters that arise are one of two possible scenarios:
1. They don't have a gap (short circuit city);
2. They don't guarantee symmetry (poor balance, poor tuning, poor response).

>The predominate attitude was that the
>capacitive coupling between the wire and the shielding material was
>the cause. I don't say the predominate attitude is correct.but, if it
>is a false assumption, then I am not the only one who needs
>revision:))

We get that traffic - yes. They suffer the same learning slope.

>If the copper pipe IS the antenna, then why have the wire inside it at
>all??

Because you have to have a conductor pair back to the receiver. The grounded "shield" serves as one half of the pair, the other spans the gap connecting to the other half's "shield" (it looks like you are shorting the inner conductor to ground) to thus pick up the opposite potential. The voltage across the gap is thus sensed and it only takes one wire. Look closely at any such standard "shielded" loop. The sense of what is being shielded is THAT conductor which you contrive to keep in a controlled environment (a coaxial shield) and away from the imbalance of nearby capacitive couplings. The "shielded" inner conductor spans a very small distance whose opposite poles' capacity is balanced to all neighboring paths to ground. That is, unless you push one side up against the wall.

Stretch out the gap of the shield loop and you have a conventional dipole. A conventional dipole exhibits high Z and high V at its tips. The middle of such a dipole has a low Z and a high I. With respect to both ends, the middle is neutral and strapping it to a conductor does nothing to change that topology (and is a common tower mounting benefit). Being curved into a loop does not change this and allows you to connect your transmission line to both sides without greatly exposing a significant length of the transmission line (and thus forcing an unbalance and upsetting the applecart).

This dipole is obviously very small with respect to its wavelength and thus some form of end loading is required. Thus the capacitor arrives on the scene. The circulating currents and potentials become astronomic for progressively smaller antennas. Those currents flow through and to the plates of the capacitor. If you don't choose the right components for that capacitor (and manufacturers of HF loops like to crow how they achieve this) then your design efficiency goes TU. Hence to speak of capacitor Q is not appropriate as the correct term is D (dissipation factor). It is certainly related (an inverse relation) and despite comments to the contrary, D is resolvable with standard bridges (although those bridges are of considerable design sophistication in maintaining balance and their own shielding - not a trivial matter).

There are simpler ways of achieving the same thing by building a completely exposed loop with capacitor (still paying attention to the ESR and keeping the whole shebang out of the mud), and simply building a shielded coupling loop. Reg has adequately described this before many times.

Owen, that info came from Roy, W7EL, who built it into the latest version of EZNEC. It has to do with the VF of insulated wire Vs uninsulated wire which affects wire antennas as well as transmission lines.

I discovered it for myself when I was building vertical loop antennas many years ago. The equation 1005/f wasn't even close using insulated wire.

For instance, my 130 foot bare copper wire dipole is resonant at 3.633 MHz according to EZNEC. Adding 0.05 inch of PE insulation drops the resonant frequency to 3.526 MHz, about a 3% drop according to EZNEC.

Thanks Richard,

I have a bunch of reading to do. Appreciate your time and the
explanation that you gave.

My receiver has a 2 to 3 ohm input impedance, my hope was to use a
series tuned loop that was entirely floating (with no ground anywhere)
and feed it to the house with a balanced line. Since it's a short run
to the house (in terms of wavelength, I had hoped the impedance
mismatch between the 90 ohm impedance twisted pair transmission line
would not produce a big loss.

The receiver input is also untuned, so the only selectivity available
to it will be the antenna selectivity, which I think I can get away
with since the antenna is relatively high Q.

Again, thanks for the info and for the web resource. I have some more
studying to do!

Regards,

T

I could perhaps scan the relevant pages of the references I
mentioned...

How are you planning to couple your 2-ohm load to your loop without
doing really bad things to its Q? (And just what sort of detector do
you have that represents a 2 ohm load?)

Cheers,
Tom

2802. A few Helical Antenna question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-26 17:07:11 UTC
From: Chris W <1qazse4@cox.net>
Message-ID: <aJO7f.119$ZP1.101@dukeread11>
Source record: 68399

I am reading the 19th edition of the ARRL Antenna Book. I am unclear which polarization to use if I want 2 Helical antennas to talk to each other. In the book it says, ". . . when two stations use helical antennas over a non reflective path, both must use antennas with the same polarization sense.." I find this could be interpreted in different ways and is not clear at all. It seems logical to me that if both antennas had the same polarization that when they faced each other they two helices would be in opposite directions and that would seem to be bad. Am I right?

It says the circumference can be between 1.33 wavelengths and .75 wavelengths. From the gain formula it would seem that the 1.33 figure would give the most gain for a given length of the antenna. Other than mechanical considerations is there any reason I wouldn't want to use the 1.33 number?

Finally, I may have missed it, but I didn't see anything that indicated how large of a wire or tube I should use for the helix. I am guessing this is just a mater of how much power I plan on feeding it with?

PS I would like to build 2 of these one is for 2.4ghz wireless network and one is 432 mhz amateur band EME and or satellite work. So the 2.4ghz version will likely never see more than 100 mW but could see as much as 1 watt. The 432 mhz version could see as much as 1000 watts, but if I did that it would be to an array of 4 of them so I guess each one would only see 250 watts?

>both antennas had the same polarization that when they faced each other
>they two helices would be in opposite directions and that would seem to
>be bad. Am I right?

On your first point, imagine you've constructed a long, long
helix that starts at your location and travels all the way to the
other station. It is logical that a wave launched by you would
then travel unimpeded along it to the far location. Now cut the
helix in the middle and turn one end around. What you will then
see is two helices rotating in the same direction, that is both
ends will have the same direction of rotation.

Can't help you with the rest unfortunately.

Cheers - Joe

"Same polarization sense" means with respect to the traveling
wavefront. When the transmitting antenna is nose to nose with the
receiving antenna, the combination will corkscrew in one sense only.

Hi Chris

I have some thoughts to share about how the CP antennas need to be
polarized, transmit and receive. But, I couldnt make any clearer than Joe
does.
Let me know if any additional text would be helpful.

Wind the two in the same "screw sense" (i.e., both clockwise out to
the far end, or both CCW out to the far end) and they will be same
sense.

The higher gains give higher sidelobes too. For earth-earth paths
that probably isn't a major issue. For satellite work it can be
significant.

Not really, any more so than with building a dipole. A popular
material for 70cm is 1/4" copper tubing, which you can easily get in
50' lengths at the hardware store. Look for refrigerator tubing in
the plumbing supply section.

True.
But for EME/Satellite work, helices are not ideal for reception.
Transmit is fine, but the sidelobe levels cause weak signal noise
problems. If the satellite has plenty of downlink power it may not be
a problem, but EME would definitely be an issue. Not to mention that
you really need switchable polarization for EME, and to do that
effectively with a helix requires two of them!

He probably measured the DC resistance at the antenna input connector. If
there's an inductance path to ground, then that's probably what he measured.
The DC resistance is NOT the RF impedance of the input.

Cheers!!!!

No, I can get them att he schools library I think. thanks for the
offer.

>How are you planning to couple your 2-ohm load to your loop without
>doing really bad things to its Q?

Is it better to convert the loop to a higher impedance just to feed it
into the house? It appears that anything I do is going to knock the
heck out of the antennas Q though.

I have not decided whether to mount the receiver at the antenna yet,
or whether to run the twisted line directly into the house from the
antenna (since it's a short run). Most likely it will have a short run
of cat 5 cable going from the antenna to a 1 to 1 toroid transformer
located in the receiver. The only selectivity for the receiver will be
the antenna itself. The receiver is very small, and uses very little
power, so it's pretty feasible to mount the entire receiver at the
antenna and run a balanced line feed of the audio into the house.

> (And just what sort of detector do
>you have that represents a 2 ohm load?)

Is it better to convert the loop to a higher impedance just to feed it
into the house?

It's an analog switch input, modified by my neighbor that gave me one
of them. The switch vendor says the switch series resistance should be
around 3 ohms, but it measures around 2.5 ohms. Probably is a little
lower than expected due to the integrating capacitors (.1 uF) which
are hung on the output of each switch. The .1's go to ground.

I measured it twice, once with a 1:1:1 isolation transformer and once
with a 6:1:1 isolation transformer....The tester looses accuracy at
low impedances, so we repeated the measurement with the generator
feeding the high impedance side of the a transformer also. I got
nearly the same reading after correcting for the transformers
impedance step down value, since both readings agree pretty well with
the switch vendors ratings, it's very likely that the receiver input
impedance is around 2 ohms.

Yes, of course they do Richard.

However, the reply was more than Dave deserved after the statement
that he made. Maybe that's how he measures receiver input impedance, I
certainly don't measure it like that.

You should have the schematic in your mailbox by the time you get this
message.

I can't post a schematic here.

Source record: 68409

The point is that the loop's inductive reactance is on the order of 10 ohms in the frequency range you're talking about. When resonated with a capacitor, if the Q is, say, 300, then the impedance at resonance will be about 3000 ohms, resistive, as seen across the capacitor. Reg's program gives you an estimate of what it will be. If you put a low-resistance load across that, the Q will drop drastically. And if you put your 2 ohms (which it won't be at the received frequency, if I understand what you have) in series with the loop and capacitor, it will also drastically lower the Q. So my question remains: how will you couple to the loop and maintain the Q?

When you measure the input impedance of your detector, you should do it while the detector is operating, and do it versus frequency. I expect you'll see a large increase in impedance at the operating frequency.

Cheers,
Tom

Thanks Reg. I had not doubt there was an effect, but it was the arbitrary percentage figure that was implied irrespective of physical parameters which could have a large range (such as your examples).

Clearly, the effect is a minor one in practical HF wire antenna cases compared to the influence of nearby structures, ground conditions etc, and one that is adequately dealt with by normal expectations of trimming length of an antenna for resonance (where that is the objective) rather than "designing" for the insulation factor.

If I am to translate the annotation correctly (and it is obviously in error - R10 and R12 are not the pair being changed), then Input Z somewhere in your frequencies of interest (you've named several) runs around 10 Ohms with the switch itself attenuating your signal by 6 to 10dB. This, of course, says nothing of the abysmal match to the antenna whose Q will be buried in potter's field.

I gather that the switch operates as a baseband quadrature/synchronous detector. It looks suspiciously like it will either short the input, or leave one half dangling, but I trust you got the schematic from a good source. I won't bother to try to verify the logic.

The roll-off frequency of the amplifier(s) is at the bottom of the AM band, it would do better to track the oscillator frequency about one seventh below so that AM signals are depressed below WWVB instead of competing with it. Increase the caps from 470pF to 3300pF.

The reason why you want low front end Input Z is to satisfy the amplifier topology (the gain will be roughly half what it is probably specified at). This could have been done better in half a dozen different ways with the same active parts.

The problem here is some bozo marked the input "antenna" and removed the necessary follower amplifier that would have been fed by the antenna which would in turn feed this circuit through the transformer. This sucker, as drawn, is going to be deaf, deaf, DEAF. If you hear WWVB it will be by virtue of their strong power, not by any quality of design here.

To unplug this design's ears and make up for the massive goof, add a FET follower. Load the FET drain with a 2.2 Ohm resistor and make sure you couple the signal through a large cap feeding the transformer. Also, bias the FET on with a hi Z divider so you don't wipe out the Q of the antenna. I will bet that even the proposed "I" and "Q" paths are mislabled or missapplied.

Tower is history - BX series ?
The 3 element beam (Cushcraft A3S?) appears to be salvageable

The other tower is still standing.

Just an extra comment Chris.

The "non reflective path" is also real important. As a circular polarised signal reflects off objects, it changes polarisation to the opposite sense. You'll find that "opposite polarised" in circular has far more (in practice) attenuation than for plane antenna cross polarisation.

If your path has an odd number of reflections you have to use the opposite polarisation at each end.

Cheers Bob VK2YQA

EME on 432 is linearly polarized (although switching polarities to make up for Faraday rotation can be advantageous) - you'll be throwing away a huge 3dB, have higher sidelobes than a well designed Yagi (nullifying the low sky temp advantage of deep space) and less gain per boom length than a good Yagi- all in all, a dismal choice for EME.

Hi Richard,

You are correct, the resistors being changed at R11 and R12, sorry for the error. To correct the statement on the schematic, consider R11 and R12 as being changed from 10 ohms to .2 ohms.

I'm not sure what the 'abysmal match to the antenna whose Q will be buried in potter's field' statement is about. With my antenna being in the 2 ohm impedance range, and the receiver being at 10 ohms (I'll use your figure), how can the match be abysmal? Granted, it's not anywhere near ideal. Have you assumed I was using a parallel tuned loop?

Since power transfer is the goal, and the antenna has a lot of ability to reject out of band signals, it was my hope to use the antenna itself as the only (purposely) tuned circuit in the system. Wouldn't converting the antenna impedance to a more traditional 50 ohms with a toroid, and then having a second toroid to convert it back down to 10 ohms also be destructive to the antenna Q and lossy?

The logic is good, trust me, the receiver as shown outperforms many much more expensive ones on the market currently. It is based on the receiver shown at:

http://www.qrp2001.freeserve.co.uk/qrp2001rf.gif

It's design has been around for awhile, the first prototype was built in 2000. While I disagree with the use of resistive matching, it should be ok at VLF as the signals are usually quite large there to begin with. For a simple receiver, it is the best answer. Although

ideally, each switch should have it's own 1 ohm variable resistor for absolute best results...the purpose being to swamp out the dynamic switch series resistance differences.

Note the receiver has no rf amp, it isn't needed. The gain is provided by some low noise op amps, and no rf stage is needed. The QRP2001 receiver is designed for 100 KHz to 30 Mhz, but it is only rated down to 1.8 MHz. However, it's worst case sensitivity is .4uV for 10 db sinad.

>The roll-off frequency of the amplifier(s) is at the bottom of the AM
>band, it would do better to track the oscillator frequency about one
>seventh below so that AM signals are depressed below WWVB instead of
>competing with it. Increase the caps from 470pF to 3300pF.
>

Agreed. Thanks.

The 470 pF value was chosen for a wide band spectral display from DC to 96 KHz, which is about the best that generic PC sound cards can do today. If the panoramic view of the surrounding spectrum wasn't necessary, these caps would be much larger in value. As it sits however, it's nice to have a panoramic view of the surrounding spectrum, so the caps might not be changed.

For my purposes, they don't need to be nearly as small as they are, but the original design was for HF...where a wiew of the surrounding spectrum was handy.

>

WRONG, but I think I understand your error. BTW, the 'bozo' was me:>:.

Again, I think you've assumed it would be fed with a parallel loop resonant antenna.

And, no active components are needed for outstanding performance.

It is possible that the antenna circuit might need to be tuned with passive components, but that possibility needs further evaluation.

>To unplug this design's ears and make up for the massive goof, add a

>wipe out the Q of the antenna. I will bet that even the proposed "I"
>and "Q" paths are mislabled or missapplied.
>

OK, this is a fair request...from someone without experience in this type of receiver. However, in reality, an rf stage of any sort is unnecessary.

Again, I think you're trying to match a 2 K parallel tuned loop to the relatively low impedance of the receiver input. I noticed you said 'follower'. Which, I think means unity gain, but is used for impedance matching.

Any active component before the audio op amp is STRONGLY DISCOURAGED in this type of receiver. This includes back to back diodes as the receiver switches can handle 4v p-p. It also includes varicap tuning diodes. A front end rf amp should be avoided at all costs, it can only degrade the performance of this type of receiver.

The receiver has incredible immunity to strong out of band signals, much more than any superhet. The nature of the beast is that the quadrature detector cancels them out by (effectively) NOT reinforcing them. The desired signal is however very strongly reinforced. Since we don't need an rf amp to get good sensitivity, any active component before the load capacitors is strongly discouraged.

Even at 60 MHz, the performance is only slightly degraded, and that is due to the inability of the analog switch to enable and disable fast enough to allow reception there. There is a commercial application using this technology that implements receive and transmit with analog switch method and it does not have an RF amp.

Of course, there is a trade off. In order to obtain immunity from strong adjacent out of band signals, we give up the ability to reject harmonics. Harmonics are only attenuated 6 db....so a tuned input must be used if the antenna cannot adequately prevent harmonics of the receiver frequency from entering the receiver.

In theory, a minimum of 6db enhancement is available because there is no mixer, so there is no conversion loss!

The susceptibility to harmonics is a small trade off. Remember, a receiver of this type is wideband, needs no conventional mixers, no detector diode, no transformers, no crystal filters, no IF amps, has no conversion loss and no major non-linear components...thus offers outstanding performance with the cost to build very much reduced (relative to a superhet). What you don't see on the schematic is the incredible sound of the receiver audio which is clean and crisp...it's not quantifiable by bench measurements however.

I've put some links to web references of this technology at the end of the message.

In the meantime, I'd appreciate comments regarding the issue of how well the loop will feed the antenna input for the modified receiver schematic I sent you by email.

Regards,

T

PS:I hope Dave is still with us. Although he probably left when he assumed I measured the input impedance with an ohm meter:>: Dave, are you able to concede that the input impedance of the receiver might be around 2 (or 10) ohms now?

If you want read up on this type of receiver, I can recommend the following:

http://www.qrp2001.freeserve.co.uk/contact.htm

http://www.flex-radio.com/

Flex-Radio makes the quadrature based SDR-1000 transceiver. For a very detailed explanation (without heavy math) of the detector theory, check out the QEX article, part 1 at:

http://www.flex-radio.com/articles_files/SDRFMP1.pdf

And, there are independent product reviews for the SDR-1000 at:

http://www.flex-radio.com/articles_files/index.htm

Dan Tayloes NC2030 high performance signle band transceiver is detailed at:

http://www.qslnet.de/member/df7tv/nc2030_pres_2004_10.pdf

The complete schematics for the NC2030 are at:

http://www.norcalqrp.org/nc2030.htm

Note that the NC2030 uses the same type of detector, but does not use a sound card and does not rely on a computer at all. It is a stand alone transceiver.

There is also a 9Y4 who home brewed a complete transceiver, details at:

http://9y4ar.tripod.com/tayloe_mixer.htm

Although slightly off topic, a low power ssb/cw exciter can be made just as easily as the receiver using the same analog switch technology. The process is simply the reverse process of the detector. To see how simple a high quality transmitter is, try:

http://www.w1tag.com/Phasing.htm

.

The calculation in the ARRL Antenna book say that a 12 foot boom with a
circumference of 1.33 wavelengths will give me a 19.9 dbi gain this
should make up for the 3 db loss I think. I haven't seen a yagi that
gives that much gain in with a 12 foot boom. The book also says that
the side lobe problem can be significantly reduced by creating an array
of 4 helical antennas. That should up the gain to 25.9 db. That's
pretty good for EME isn't it? Take it to 16 and you get over 30 db
gain. And the only need to be spaced at 1.5 wavelengths, that's only
3.4 feet.

No it makes perfect sense, I don't know what I was thinking. I mean if
you take 2 right hand threaded bolts and have them face each other they
are still right hand threaded and a nut will go of one and right on to
the other spinning the same way. It's obvious now that I think about it.

Owen,

You're right of course. Although there is a balance needed as the complete details would fill a small book...no one would read it to the very end.

Check the thread a little later in it's history, I think there has been additional pertinent information goven.

Enjoy.

2824. Problem with nec2

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-27 19:08:49 UTC
From: Detlef Conradin <skyline@despammed.com>
Message-ID: <436125c1$0$1163$5402220f@news.sunrise.ch>
Source record: 68421

Hi

To get started with nec2 I tried to simulate a simple dipole.
The graphical view of the pattern looks okay, however the gain seems
to be to high. To what are the DBs refered in the output file?
Or what do I have to change to get the gain in dBi ?

Here is my input file:

```
----------------------------------------
CM Test
CE
GW 1 20 0 0.005 0 0 7.5 0 0.01
GW 2 20 0 -0.005 0 0 -7.5 0 0.01
GW 3 1 0 -0.005 0 0 0.005 0 0.01
GE 0
EX 0 3 1 1 10. 0 0 0 0 0
FR 0 30 0 0 6. 1. 0 0 0 0
RP 0 37 72 1001 0. 0. 5. 5. 1000 1.
EN
----------------------------------------
```

Detlef

PS:
If I calculate the gain with the formula:

$$\text{Gain} = \frac{4 * \text{Pi} * r^2 * |E|^2}{P_{in} * 2 * 120 * \text{Pi}}$$

by using the E-Field magnitude values from nec2's output I get also
those very high values. (?)

> Chris W

The closest optimized Yagi I found was a K1FO on a 14' boom- 17.9dBi which
compares quite well with your 19.9dBi on a 12' boom once we adjust for the
polarization loss making the helical 16.9dBi linear for the helix vs. 17.9dB
for the K1FO My experience with EME is at 23cM where we use dishes- but I
can tell you that 1dB is to kill for..
The circularity could be an advantage as it would be insensitive to Faraday.
Another advantage is that they are non critical to build- at least from a

gain standpoint. But I think the real issue will be weight and weight ditribution. Between the helical tubing, non conductive boom and the reflector screen a helix is going to be a clydesdale compared to a Yagi. Another problem might be the necessity to mount the array from behind the reflector- that's going to be quite a moment arm.

Bottom line is, 432 MHz EME is well explored- I am not aware of the use of helices for EME there- although, again I am not active on 432 EME. If they are not being use, there's probably a reason.

Chris W. wrote:
"I am unclear which polarization to use if I want 2 helical antennas to talk to each other."

Unless you are bouncing the signals off a reflector, use the same polarization for both.

The axial-mode helical antenna is circulaly polarized and fires along its axis away from its ground screen. It can be either left handed or right handed depending on which way the helix twists. It responds to vertical, horizontal or diagonally polarized waves. It does not respond to waves with the opposite twist to its helix. Circular polarization of the opposite twist is rejected.

This is like machine bolt threads. A bolt can screw into a nut from either side if it has the same itch direction, but a left hand bolt won`t screw into a right hand nut. Circular polarization of the opposite rotation is rejected.

Refer to any edition of "Antennas" by Kraus for the details. Kraus invented the helical antenna after other experts said it could not work.

Best regards, Richard Harrison, KB5WZI

>your figure), how can the match be abysmal?

Even allowing for the values you offer (they are wrong) you have a 5:1
mismatch. Your actual mismatch is Q times that.

>Granted, it's not anywhere
>near ideal. Have you assumed I was using a parallel tuned loop?

Tom has already carried the water describing what your antenna Z looks
like. It is orders of magnitude greater by virtue of unloaded Q. You
want to aspire to make your receiver match that as closely as possible
- this design does not. What you have is a heavy, heavy load that all
but wipes out the advantage of Q.

>Since power transfer is the goal, and the antenna has a lot of ability
>to reject out of band signals,

Not any more.

>it was my hope to use the antenna
>itself as the only (purposely) tuned circuit in the system. Wouldn't
>converting the antenna impedance to a more traditional 50 ohms with a
>toroid, and then having a second toroid to convert it back down to 10
>ohms also be destructive to the antenna Q and lossy?

2 Ohms, 10 Ohms, 50 Ohms are all still very trivial in comparison to
what the antenna has to offer. At the danger of introducing an
analogy, you have a 1.2 liter high performance race car which needs to
turn 14K RPM for 300 HP and you've put it to hauling a 40 foot fifth
wheel trailer. You are not even going to pull that load a foot before
you burn out the clutch.

>Although
>ideally, each switch should have it's own 1 ohm variable resistor for
>absolute best results...the purpose being to swamp out the dynamic
>switch series resistance differences.

You are arguing precision at the wrong end of the scale. Any
additional resistors are burning signal up and any appeal to
technicalities has been lifted from other applications that don't even
come close to this situation. I've been designing with these switches
for 25 years, and for very small signals.

>Note the receiver has no rf amp, it isn't needed. The gain is provided

>receiver is designed for 100 KHz to 30 Mhz, but it is only rated down
>to 1.8 MHz. However, it's worst case sensitivity is .4uV for 10 db
>sinad.

This is comparing apples and donuts when the menu only offers steak.

First, all these glowing accounts of excellent performance come from
European sources where VLF is far more common, and those services pour
up to a MW into the air. Your fillings would work just as well.
Second, your glowing reports are about HF characteristics with
conventionally sized antennas. When you attempt to extrapolate this
to VLF, you are not carrying the decimal point of inefficiency to the
left as you drop down in frequency.

>Again, I think you've assumed it would be fed with a parallel loop
>resonant antenna.

You haven't described anything else, and no appeal to series resonant
is going to resolve Q going down the toilet. Loss is loss no matter
what topology. This was the point of discussion with ESR.

>And, no active components are needed for outstanding performance.

And yet you were the first to offer some builders have experienced
miserable results. You are about to join that pouting crew. On the
other hand, as I've suggested, you may still get WWVB with all these
problems - even wrist watches do. In that eventuality you have no
real basis of comparison and your only feeling would naturally be one
of wonder and awe. An aw shucks glow in the eyes does not translate
to a marvelous DX receiver.

>Again, I think you're trying to match a 2 K parallel tuned loop to the
>relatively low impedance of the receiver input. I noticed you said
>'follower'. Which, I think means unity gain, but is used for impedance
>matching.

Exactly.

>Any active component before the audio op amp is STRONGLY
>DISCOURAGED in this type of receiver. This includes back to back
>diodes as the receiver switches can handle 4v p-p. It also includes
>varicap tuning diodes. A front end rf amp should be avoided at all
>costs, it can only degrade the performance of this type of receiver.

This only applies in the face of strong signals being applied to such
an amp. Yes, you have guaranteed that with the abysmal match and all
these Cassandra forecasts come true.

>The receiver has incredible immunity to strong out of band signals,

This comes only from Q. This is a baseband receiver which means it is
open to all frequencies. Thus the necessity of a hi Q passive front
end (you killed it). What you call immunity is a product of dynamic

range capability and what circuits that follow this detector.

>The nature of the beast is that the
>quadrature detector cancels them out by (effectively) NOT reinforcing
>them.

No, you've gotten very poor instruction on the qualities of this type of detector. I was designing them 35 years ago and they are used in a bajillion TVs. Absolutely every one of them has front end electronics.

The detector neither cancels nor reinforces, it provides a phased output. The detector also has its points of failure too, but when all the necessary pre-conditions are met, it has many more features and immunities. You have described none of these.

>What you don't see on the schematic is the
>incredible sound of the receiver audio which is clean and crisp...it's
>not quantifiable by bench measurements however.

This is simply absurd. The very qualities you describe are measured every day and are the purpose of this style of detection's use. However, as you describe them, you still give the appearance of not knowing what to do with the "I" and "Q" channels. Therein lies the difference.

I would also offer, that among all your attached references, much less your own discussion, absolutely nothing is said about the "I" and "Q" channels. These outputs (why two?) are pushed into a black box, and one AM signal emerges which begins to argue: what is being detected? and where? I especially like these ace buster questions because it is overwhelmingly obvious that no one actually knows what the "I" and "Q" channels are for. They can be put to work without any more fuss than amplifying them, but instead they are pushed into equations, software and black boxes.

What is worse, I have yet to see anyone actually offer what forms of modulation can be detected - there is a serious gap of research in all these articles you've offered. For so many that have come here to breathlessly announce the miracle of the Tayloe mixer, to a person, they don't even know a fourth of what could be done.

>I've put some links to web references of this technology at the end of
>the message.

All very nice commercials, and one offers the nuts and bolts of the practical detector that must have missed your attention as it contradicts with:
"First, the RF input signal is bandpass filtered and applied to the two parallel mixer channels."

In fact, and as I've experienced through 30+ years of their design, there are filters all around.

Your having snubbed the antenna Q violates this first premise. Then we look at the "I" and "Q" channels, the only way to achieve what you describe as the marvelous characteristic of
>The receiver has incredible immunity to strong out of band signals is achieved by conventional filtering just like in the superhet. In fact one of your references employs a nine pole Butterworth. Another design has cascading filters out to eleven poles. This being a baseband converter has simply shoved the filtering into the AF band. Out of band performance only applies for those who cannot hear dog-whistles. In short, a technological shell game. Effective, certainly, but not unheard of - direct conversion was the original form of receiver.

Going further, the QEX article accurately describing the Tayloe detector describes the purpose of the capacitors in the circuit you sent me. Problem there is that your lowered RC constants are running out at 1ï¿½S for samples being taken at a much slower rate. Result is a serious droop is occurring.

>schematic I sent you by email.

Didn't get it. My Kill filters barely let your last schematic through.

Hi Trabem

I've been trying to follow this thread because I like to play with tuned
loop antennas for broadcast band reception.
I missed the part about how much this 20 meters of #2 copper cable with
its support weighs. Your project sounds Serious. That antenna must weigh
close to 500 pounds
The loop antennas I've been building are large diameter coils of smaller
wire. I recognize that the type antenna I build arent acceptable for your
consideration. But, I do have some experience with using a low freq loop
in the city. If you are located near man made noise, it is very likely
that resonating the loop doesnt result in highest Signal/Noise ratio.
Perhaps you already have experience with Low Freq loops and can tell me
about your experiences. I am interested in learning.

Jerry

What kinds of steak are on the menu? I haven't had lunch yet and I could go for a nice Chateaubriand.

By the way, some kinds of donuts have apples in them. Apple fritters I think they call them. In a way they're both apple AND donut - since you brought it up.

Hi, you have a segment length violation in TAG 3; it is very short, being only 5mm. Also short when compared to the segment length in TAGs 1 and 2 at 37.5 cm. It is a good idea to maintain equal segment lengths in the entire model, with minimum lengths not exceeding 0.001 wavelengths on any frequency. I have modified your code as shown below. There is nothing wrong with breaking the wire up into three tags, but they should all run the same way. Your end TAGs are running in opposite directions, which will cause current discontinuities in plots, and NEC output file data.

There was something weird about your RP card also, but have not yet delved into what is wrong. I have not checked, but your computation of gain with the E-field should now be correct.

Cebik's book on NEC modelling, at www.nittany-scientific.com, for $50 is well worth the money.

PS, also confused by your formula. Which Value of E are you using? Are you
trying to calculate the "Total radiated power" (TRP)? If so you need to
integrate the power density over a spherical region. The calculation is
greatly simplified if you take advantage of any natural symetry in the
radiation pattern -- i.e. integrate from axis end to axis end, then multiply
by 2*PI -- as in elementary calculus, you are using a single integral for a
"Solids of revolution" method, instead of a double (Surface integral).

If you are trying to caluculate the gain in a given direction you need to take 20*log(E/Ei). Where E is the NEC calculated E field in the desired direction, and Ei is the computed E field from an ideal isotropic source with the same input power as the test antenna.

As for your RP card, I notice that you are attempting to vary both "Theta" and "Phi". I usually keep one fixed and vary the other, but to be honest I am not sure if what you are doing is incorrect, although I notice that the "Phi" pattern is only computed for one frequency. The only other difference is that I normally do not use gain averaging. Also using 1 degree increments does not seem to slow things down very much. With your RP card I was also getting some weird pattern discontinuities.

Frank

OK Richard,

I like to think I'm not stupid, but reading your last message.......

That being said....

I just went through and reread every single word in this entire thread including all the replies and I have the following questions:

I have a series resonant loop with moderately large conductor wire and reasonably high Q capacitors. It's tuned to resonate at 60 KHz.

A series tuned circuit is a low impedance circuit, so 60 KHz signals from the antenna are passed to the receiver and other frequency signals are attenuated as the X(C) or X(L) on either side of the resonance frequency attenuates them. Using Reg's rjeloop3 we get 25.4 uH for the loop inductance, and it resonates at 60 KHz with 286,700 pF. It also gives us the X(L), which is 9 ohms and (presumably) the X(C) is -9 ohms. It estimates Q at 221. The 2 reactances are equal and opposite, they cancel each other out. This leaving us with the effective R(ac) for the loop inductance and the effective R(ac) of the resonating C. The sum of these 2 resistances gives us the net impedance of the loop. I know that the ESR of the cap is in the milliohm range and the same for the wire, but I don't know the actual impedance of loop. For a parallel tuned loop, Reg's program gives me a value of 2K ohms. I don't really know what the value is for a series tuned loop such as I will have.

Why does this make my antenna look like 2 K ohms impedance? I was (admittedly guessing) that it looked more like 2 ohms. Maybe 2 ohms isn't right, but can the impedance of a series tuned loop made out of number 2 copper and low ESR caps be 2 K ohms??

My receiver measures around 2.5 ohms input impedance, verified by 2 different test methods...maybe that's not absolutely accurate. But, you said it should have looked like 10 ohms instead. I accepted your number however, let's say it's a 10 ohm impedance input from now on.

I believe that the antenna and receiver should be designed for maximum power transfer which means making the antenna and the receiver front end equal with regard to impedance. Is this correct? Is maximum power transfer indeed my goal?

Regarding the integrating caps C value:

Yes, I understand I've lowered the effective series resistance (by modifying the input circuit) that charges and discharges the integrating caps. And, yes, I know different values of caps will be needed. And, NO, I haven't addressed that issue yet. But, thank you for pointing it out to me. I had thought these caps should be greater than 1 uF and possibly larger. At this time, it's not a priority as Winter is coming here and I have to get the antenna installed and tuned. Fine tuning the receiver will come in the Winter when VHF quiets down and the snow is 10 feet deep in the woods. For now, the priority is making sure the antenna is all set before the snow flies. Thank you again for reminding me that the integrating caps need to be a different value. Since I might have to have a different input circuit, or even an tuned circuit in the front end, I don't want to address this issue now.

So, how do I fix it??

I'd be perfectly happy redoing the input circuit for 50 ohms input impedance and putting some selectivity back into the front end if that's what it takes to have the receiver function. My idea of matching a 2 ohm impedance antenna to a 2 ohm impedance receiver without any tuning at all (other than the loop antenna) was just that, an 'idea'. If it doesn't work, then it doesn't work. But, on the surface, it seems reasonable. It appears the major problem here is that you think my antenna impedance is 2K and I think it's 2 ohms (or less). So further discussion is a waste of time and bandwidth (until this issue is resolved).

My primary question is about the impedance of a loop antenna made out of 20 meters of #2 copper in series with each other using low esr caps and tuned to resonance at 60 KHz.

>>schematic I sent you by email.
>
>Didn't get it. My Kill filters barely let your last schematic
>through.
>

Not sure what I did to deserve an honored position in your kill file. I confess to being stubborn and cranky, but I don't think I was disrespectful or made inappropriate comments. I won't email you anymore schematics.

Obviously, if I had all the answers, I wouldn't need to ask here. If you could shed some light on the series tuned antenna impedance and Q, it would help me to make forward progress and I'd appreciate it. Where

have I gone wrong?

>resonated. Are you not taking the output across the ends of the loop
>(across the capacitor)?

No, you are describing a parallel tuned loop, aren't you Tom,

That is NOT what I'm trying to build.

I am planning a series tuned loop, which is C in series with L and the output is taken across the unused loop terminal and the unused cap terminal.

I think it should be called a series tuned loop, shouldn't it?

I know I suggested a whole bunch of times that your 2K loop impedance sounded like a parallel tuned loop value and you keep insisting that my series tuned loop will have an impedance of 2K ohms.

You also told me that "Tom has already carried the water describing what your antenna Z looks like". I suggested that perhaps Tom and you thought I was referring to a parallel tuned loop and said several times that it was a series tuned loop.

Then you ranted on and on or maybe I ranted........

Did Tom and you not hear me when I said it was a series tuned loop or did I not make it plain enough.

Isn't the impedance of a series tuned circuit LOW at resonance??? It was when I went to school.

If I've err'd, please let me know how.

Thank you.

T

PS:

And, yes......I expect the Q to be cut in half if I attach a receiver and a loop with identical impedances to each other. I call it loaded Q and it's a necessary evil if one doesn't want to resort to electronic (active component) impedance matching.

Put another way, if my receiver had a 50 ohm input impedance and my loop had a 50 ohm output impedance (with a Q of 100, unloaded), I'd

expect to have a (net) Q of 50 after the receiver was connected to the antenna.

Reg's software tells me I have a Q of around 221. I assume that's net Q for the loop itself (unloaded). If my receiver is made to have the same Q as the loop, then I expect the loaded Q to be around 110 after they are connected together.

I know you mentioned an active buffer amp to transform impedances. No doubt this would help to keep the loaded Q up, but I'd like to avoid any active antenna preamp/rf stage if possible......as previously discussed.

>And with a skin depth of about 0.01" at 60kHz

>

I thought about litz, and it probably would have been cheaper than the copper welding cable I bought. But it's fragile in the outdoors and breaks easy when the wind blows it especially in long spans like I am going to have. Rather than encase it in some sort of protected sheath, I decided to use the welding cable.

>Consider that Q is energy stored divided by energy dissipated per

Is that to mean the loop circuit consists of an inductor (including its radiation resistance and copper losses) of about j10 ohms and a capacitor (including its losses) of about -j10 ohms and a load resistance (being the 2 to 10 ohms receiver input Z) in series (ignoring transmission line for the moment)?

You quote a Q figure and talk about expected bandwidth earlier in the thread. Wary of making any unwarranted assumptions, is it safe to assume that you know that it is the loaded Q that will determine the bandwidth of the circuit in operation?

If you insert the rx input Z in series in the loop as described above, you don't need a calculator to see that the loaded Q cannot be 200+, and you might be lucky if it is better than 5 if the numbers you have quoted are correct. This circuit is not likely to give you much front end selectivity, is it?

Perhaps you need to consult a textbook to review your understanding of unloaded Q, loaded Q, efficiency, and bandwidth, and where to apply which Q value.

>May I ask, what is with the almost fanitical adherence to Q?

Sure, it's a fair question.

I have a simple receiver with a low impedance input that is few with a
toroid transformer and a tuned circuit to match the impedances and to
keep out of band signals out.

I want to convert the receiver from HF to VLF (60 KHz) and to use a
series tuned loop of high Q as an antenna. In order to simplify the
receiver input, I have mentioned as an option to eliminate the 50 ohm
matching transformer and the tuned circuit in the front end of the
receiver....and to feed it directly with my low impedance loop. In
this way, the loops high Q would serve as the only means of preventing
out of band signals from getting into the receiver.

In order to make sure that actually happens, I suggested making the
loop Q as high as possible.

Hence my 'almost fanatical adherence to Q'

Not sure if it will work, but wanted to run it past the group.

Regards,

T

A series resonant loop. First, this is a contradiction in terms and
as your interpretations hinge upon this reading, it bears examination.

>A series tuned circuit is a low impedance circuit, so 60 KHz signals
>from the antenna are passed to the receiver

To be in series, you have to describe the source and its common, you
simply describe the loop. With this, you neglect the coupling between
the actual source of power, a remote transmitter, and the antenna's
Radiation Resistance. This value appears no where in your analysis
and yet it is largely responsible for the atrocious efficiency of this
breed of antenna.

I've thrown together a quick model of your 5M on a side loop using
(and being generous) #1 wire. The bottom of the loop is 10M above
ground. In terms of performance relative to an isotropic antenna it
is down 60dB. It displays an impedance of:
Impedance = 0.05849 + J 10.37 ohms
An addition of a 0.2555ï¿½F capacitor draws this down to:
Impedance = 0.05851 + J 0.006073 ohms

Please note that the capacitor is perfect, no ESR whatever. In a
system with Zc = 0.0585, this antenna presents a 1.11 SWR. The half
power points of its resonance are only 600 Hz apart. Hence a Q of
100.

This is without any extraneous detector circuitry whatever. We will
see where its addition leads.

By simply inserting your 2 Ohms (I know full well where my 10 Ohms
will take us) - in series - (again, your thesis) and re-assigning the
system Zc to that same 2 Ohms, this antenna presents a 1.077 SWR.

Sounds hunky-dory, right? Except when you look at the Q which has
plunged to 2.9 and the antenna loss now compares to -75dB compared to
an isotropic.

Your receiver, in series with the loop, has just killed 15dB of gain
and wiped out the Q by 95%. Not bad for a day's work.

I will forgo the remainder of your questions to allow you to digest
the material above. You can validate these readings by using EZNEC
which in its free version is perfectly suitable to this question.

This is not the kill file of unsophisticates simply ignoring by posting name. Agent has much more flexibility to read headers and judge what is spam. Works great and eliminates that source by - well I cannot guess the amount simply because I don't count the kills, and none survive the trash can except those at a lower level of sifting.

I'm getting a lot of correspondence right now helping designers out. About half a dozen posts a day. Seems to be peak season and their mail lands in my inbox without incident.

>I confess to being stubborn and cranky, but I don't think I was

>anymore schematics.

I simply pointed out I've only receive one of your emails, and the kill files put it in the trashcan - that is one step above absolutely erasing it. The presumption from the several kill-rules is that your headers appear to be spoofed. Now, tell me that you aren't doing something out of the ordinary like passing mail through an open relay. ;-)

Hi Owen,

Hi Owen,

I am using large copper cable and relatively low loss capacitors. I expect the 9 ohms of inductive reactance to cancel out the -9 ohms of capacitive reactance leaving only the sum of the AC (or RF) resistance of the copper and the ac resistance of caps to give me my net impedance. Am I correct up to this point??

I'm trying to take this step by step so I can understand where I've gone wrong.....clearly I must have made an error somewhere.

I don't know what the actual ac resistance of the caps is, but I do know the ac resistance of 20 meters of #2/0 copper welding cable is pretty damn low.

Yes, the loop is series tuned, so the output is taken on the unconnected capacitor terminal and the unconnected wire end.

Rjeloop3 gives estimates my Q at 221 even though it thinks I'm building a parallel tuned loop. But, I think Q is Q, and the Q of both types of loops is the same provided the same materials have been used in both loops.

I am (for now) not considering the effects of hooking it to a receiver and/or the transmission line. I confess I have not tried to quantify the actual values of the ac resistance of the copper and have only rough estimates of what the esr of the caps is. I'd be pretty surprised if the dc resistance of the cable is much more than .1 ohms though, so the ac resistance should be a little higher at 60 KHz.

Can you estimate what the unloaded Q of the loop is (in round numbers), and if so, can you agree that it might be around 221 (as Reg's software predicts)? Can you estimate what the impedance of the loop is (in round numbers)? Again, do not factor in the receiver input impedance as we aren't sure whether I'll keep it as is or match it's impedance with a preamp and/or toroidal transformer. For the moment, assume the receiver is mounted at the loop (which is a very real possibility since it's fairly small).

Thanks for jumping in.

T

Forget Rjeloop3 for the moment and think about what you have.

You focus on how low the resistance of the loop inductance is, and whether or not the capacitor ESR is significant... neither is when you jam a 2 ohms receiver in series with it all (ignoring the transmission line).

You seem to be analysing your series circuit with part of it (the rx) replaced with a s/c.

>I am (for now) not considering the effects of hooking it to a receiver

Read Richard's response, though it is more detailed and no doubt more accuracy.

I think you will understand the problem when you analyse a three component series circuit (your topology), the Loop L, the Loop C and the Rx input z. (You can ignore radiation resistance, loop loss, capacitor loss, they are all much less than rx input z so the loops loss is dominated by the rx input z in your circuit.)

The place this will end up is that you will come to realise that knowing how the L and C of the loop behave unloaded, and dwelling on that behaviour ignoring the effect of loading is probably why you are where you are (an assumption I know).

When you have worked that out, you may understand why others are asking how you are going to couple to the loop. Your proposal to insert the 2 ohms (or whatever) rx input in series with the loop components isn't delivering what you wanted, and it won't matter how thick the loop conductor is, or how low the ESR of the capacitor is.

In a series resonant circuit, at resonance it is equivalent to a dead short (disregarding the R of the circuit). Series resonant circuits are usually used as traps. To develop a voltage one needs a parallel resonant circuit at the resonant frequency, The Q will simply determine how quickly the voltage falls off each side of resonance.

Next there are two types of Q, first the calculated unloaded Q and second the in circuit or loaded Q.

I think you are heading down the wrong path with the series circuit as your fighting a loosing battle. Assuming a perfect coil and capacitor you create an infinite Q circuit. Now you hook it up in your circuit. First there has to be enough resistance to develop the voltage , and here is the rub, as you increase the resistance to develop a voltage you decrease the Q. Yuk!

Go with a parallel circuit like the rest of the world uses and you will be going in the right direction.

OK, now we're making progress. I knew there had to be an explanation for your insistence that the antenna presented a 2K impedance to the feedline! I absolutely knew it could not be correct and you were equally determined:>:

Let me describe exactly what I hope to build, and you can enlighten me regarding what the proper term is. Thanks for hanging in there, the road was a little bumpy....

I'm thinking feedline attached to one end of the wire. The other end of the wire is attached to the capacitor bank. The other side of the capacitor bank is attached to the other feedline terminal. Or, stated another way, the cap is in series with the wire and the 2 transmission line terminals are connected to the left over cap and the unused wire end.

OK, but I hadn't thought this entered into the calculations of the loop.....it is what it is and we all know it's too damn short and too damn close to the ground to be efficient. At 60 Khz, there is so little difference between 5 feet off the ground and 50 feet off the ground, that I guess I never thought it mattered much...and, so tended to skip over these details. Any antenna that I can build with my budget will never be efficient:>: Is this a fatal error, or do I really need to look at this issue to proceed?

I understand these types of shortened antenna are often less than .001 percent efficient because they are so short relative to the wavelength being transmitted or received.

>system Zc to that same 2 Ohms, this antenna presents a 1.077 SWR.
>

OK, I'm not completely understanding the last paragraph. Have we abandoned the .06 + j10 real loop impedance and/or are we talking only about feeding a 2 ohm impedance loop into a 2 ohm impedance receiver (which seems to be a match made in heaven at first glance)?

If we aren't considering the .06 j10 anymore, are you trying to impress upon me that even a perfectly matched 2 ohm antenna connected to a 2 ohm impedance receiver knocks the Hell out of the Q by that large of a factor?? If so, I can understand the need for the buffer follower you suggested earlier!!

Send me a sign, I sense an incoming lightening bolt::>

Another user just suggested I think of Q as stored energy and that anything that consumed that energy severely lowers the Q. I can understand that since the goal of the impedance matching is to transfer as much of the stored energy as possible. Further, if this is the case, it seems an active antenna matching buffer amp (impedance shifter) is necessary when using a loop of the type I planned. Not sure whether I am getting it or going off on another tangent....like I said above, send me a sign:>:

>Sounds hunky-dory, right? Except when you look at the Q which has
>plunged to 2.9 and the antenna loss now compares to -75dB compared to
>an isotropic.
>

>Your receiver, in series with the loop, has just killed 15dB of gain
>and wiped out the Q by 95%. Not bad for a day's work.
>
>I will forgo the remainder of your questions to allow you to digest
>the material above.

Yes, please do forgo, for the moment anyway..... Please specify whether you are explaining a 2 ohm impedance loop hooked to a 2 ohm impedance front end (in the preceding paragraph). Then, we can proceed I think..... I'm trying to assume NOTHING. Please forgive me if I seem to need a lot of clarification.

>>Not sure what I did to deserve an honored position in your kill file.
>
>This is not the kill file of unsophisticates simply ignoring by
>posting name. Agent has much more flexibility to read headers and
>judge what is spam.................

OK, understand. When you made the original comment, I thought you were saying I had done something purposely inappropriate. I use Eudora in order to avoid the Bill Gates problem, so I understand the difference between sorting to the trash and sorting to the junk mailbox! Trash is trash, gets emptied forever when I close the program. Junk is possibly trash, but doesn't fit all the criteria, so it's saved (just in case it really isn't garbage).

Got yah.

>your
>headers appear to be spoofed. Now, tell me that you aren't doing
>something out of the ordinary like passing mail through an open relay.
>

Well, I'm not sure how and what happens after I hit the send button. To the best of my knowledge, I am not doing anything of that nature. It's (my email) a paid service, so it should be on the up and up. Is it possible it might be a DSL issue, where the IP address is masked to some extent?

Thanks for hangin in there.

I think I'm starting to get it. Am I cutting off my foot to spite my
face::>

Comments made by you and a few others have nudged mein the right
direction.....

The higher I make the series resonant Q, the lower the impedance goes,
hence it's almost impossible to get a lot of voltage out of it??

Not sure why it matters that much. But, I was under the impression
that a perfectly matched antenna and front end would only decrease the
Q by a factor of 2.

Follow along with Richard's comments if you like and add your comments
as I check here often and read everything, sometimes many mant y
times:>:

Regards,

T

PS:I had begun thinking that the higher imedance presented by a
parallel loop was harder to match with a balun, which is why I started
thinking of a series loop. I'm gettin there, thansk again.

I'm not sure you missed that much, I'm possibly on the right track
though.

> I missed the part about how much this 20 meters of #2 copper cable with
>its support weighs. Your project sounds Serious. That antenna must weigh
>close to 500 pounds

No, not all. It's a little heavy, but we have big tall hard wood
forest here and my main concern is not weight, it's the ice that
happens in Winter. So, lighter wire would never survive.

>that resonating the loop doesnt result in highest Signal/Noise ratio.

I understand this. But, I live quite a distance from any city and the
distances to my neighbors is measured in hundreds of feet. It's quite
rural. If I suspect there is a source of noise in the house, I have
access to the high voltage (pole mounted disconnect) and can shut the
power off to my house from a switch 900 feet from the house. If the
noise persists, it isn't a local noise source:>:

> Perhaps you already have experience with Low Freq loops and can tell me

>loss is dominated by the rx input z in your circuit.)

So... if you did this, and you want the loop to give you front end selectivity, and you want the bandwidth to be xxx which led you to want the LOADED Q to be 100 or more (whatever), you now know that the load introduced by the receiver into the series loop you have dictated needs to be better than (<) XL/Qloaded or < 0.1 ohms (not twenty or more times that value).

How can you deliver a load impedance to the loop derived from the rx input circuit and its transmission line that is efficient and less than 100 milliohms (at the loop)?

Is your single turn series loop idea practical at 60KHz?

Owen

Fine, but it doesn't really matter. The unloaded Q is one thing, the
loaded Q that is seriously depressed is another.

>OK, but I hadn't thought this entered into the calculations of the

You have so little efficiency, that the proximity of ground hardly
matters (you already know this) - until we look at the lobe pattern,
balance, and that side of the coin.

>or do I really need to look at this issue to proceed?

You do your best - you are not that far from it. The loop allows you
to end load it better than using a dipole with coils.

>about feeding a 2 ohm impedance loop into a 2 ohm impedance receiver

You have injected 2 Ohms into the series circuit - it is now part of
the antenna even if it inside the receiver.

>(which seems to be a match made in heaven at first glance)?

Simply a slight of hand, mathematically. You have to pick a reference
you call Zc (characteristic impedance) of something, and your
resistance is wedded to the antenna. However, the reality of it is
that the native loop compared to the actual load is severely
mismatched. You don't lose 15dB gain on the stairway to heaven. Most
would parallel a loop's capacitor with a really big resistive input Z
match to preserve Q. You chose a path that is leading to grief.

>Send me a sign, I sense an incoming lightening bolt::>

ZAP

A series load in a circuit that is heavily laden with current requires
a very, very small value. Your switches are deadly elements even if
they are the best in the market.

That same circuit, sans series detection, also supports high voltages
courtesy of Q. At this frequency you have a world of components that
can tap them without seriously loading the circuit and killing the Q,
and the voltage, and the efficiency.

Hence a follower ACROSS the capacitors and AT the loop driving the
line back to the detector. A follower that presents 20K or even 2000K
Ohm load to the loop at 60KHz is a walk in the park. You aren't going
to recover that initial 60dB plunge from the size of the antenna, but
you don't have to grease the slide for another 15dB plummet.

Still, and all, there's always the practical reality that the design
will work out of the box. Wrist watches do it. It won't be the best,
but there's not much competition and this isn't DX we are talking
about, unless you want to work Europe's VLF (and even then you may
hear signals).

You still haven't bitten the bait on what makes the "I" and "Q"
channels useful beyond cramming them into black boxes to strip away
the only really useful angle (pun intended) they offer - phase

information. This is in fact the single most fascinating aspect of
the detectors.

==========
Trabem,

This discussion is getting you nowhere very fast.
So let's summarise.

I don't have your exact dimensions but the following are good enough.

L = 27uH, Reactance = j10 ohms, Conductor loss = 0.05 ohms, ESR =
0.01 ohms, Radiation ohms = 0. Receiver input = 10 ohms, Ground
loss ohms = 0.01

The intrinsic Q of the loop is 10 / 0.05 = 200.

The working Q of the loop, when series connected, is Reactance divided
by the SUM of all resistances including the receiver.

Working Q = Reactance / (0.05 + 0.01 + 10 + .01) = 10 / 10.07 =
0.993

Take note of the ridiculous low value of working Q due to the loop
being in series with the receiver.

>> those very high values. (?)

> PS, also confused by your formula. Which Value of E are you using? Are you
The formula should be correct:
I just use the magnitude value of the E Field. The intensitiy
W_rad is then 0.5 * |E|^2 / Z_w (E and H are in phase and
orthogonal in the far field)

The radiation density U is then r^2 * W_rad (Unit: Watt per solid angle)

The radiation density U_0 of an isotropic radiator with a total radiated
power P_rad is: P_rad / (4 * Pi).

The gain is then U/U_0 (or in dBi: 10*log(U/U_0)).

> trying to calculate the "Total radiated power" (TRP)? If so you need to
> integrate the power density over a spherical region. The calculation is
Yes, but nec2 shows the total radiated power in its output.

> and "Phi". I usually keep one fixed and vary the other, but to be honest I
> am not sure if what you are doing is incorrect, although I notice that the
> "Phi" pattern is only computed for one frequency. The only other difference
No thats no true. In the output file I can see E_phi as well as E_theta for
every combination of phi and theta (for every frequency).
I use the programm Xnecview to view the pattern and it has problems if you
don't have points over the full sphere.

> is that I normally do not use gain averaging. Also using 1 degree
The average gain (over the full sphere) should probably be 1 (or 0 dBi).
I get 0.991.

Thanks for you help! The bad computation was caused by the stupid
segementation I had chosen.

Detlef

Very interesting Detlef. I must admit I did not study the formula too closely, so will look at it again, to be sure I understand it.

My version of NEC2 has a built in NEC-View utility (NEC-Win Pro), so am not familiar with Xnecview. I will try your full spherical pattern RP card, and see if I can run it. When I first cut and pasted your code I was getting strange FORTRAN code error messages -- something I have never seen before -- and the program was locking up (Windows XP OS). Modifying the RP card cured the lock up problems. Examination of the segment currents would also probably have indicated the segmentation problem area. At 1 degree intervals the NEC output file would be huge, so can see why you chose 5 degree increments.

As for "Total radiated power" (TRP) I assume you mean the "Power budget" output. I had thought this is only valid for free space computations. With antennas placed close to the ground the "Power budget" only seems to account for copper losses. Just a minute, now you have made me start thinking. My "Network Loss" line in the power budget output always shows zero. Did I miss something? Do I have to invoke something in the RP card to make "Network loss" non-zero, and thus arrive at a true TRP. Heck! To think all this time I have been running Excel numerical integration routines to determine the TRP.

Regards,

Frank

Source record: 68449

OK Richard, it looks like the lights are beginning to come on and I'm on a different road (a road that doesn't end in a fiery disaster).

At the risk of jumping to far ahead......

Let me know if this is correct or not......

Let's dump the series loop, it doesn't sound promising:>:

So I'm (now) using the same wire and the same resonating C, but it's in a parallel configuration. My loop is 2K impedance, my receiver is 50 ohms (more conventional although maybe not necessarily tuned, TBD).

Is my mission to purposely isolate the loop so that anything happening in the receiver doesn't impact the loops Q? To maintain the best possible Q, would I mismatch the antenna to preamp impedance on purpose, providing a 50K or even 100K input impedance buffer, so as not to suck power out of the loop? And, should the output of the buffer present an approximate 50 ohm output impedance, therefore matching the input impedance of the RX (for best power transfer)? If this is the case, an active buffer amp seems inevitable.

You gave me numbers for a 2 ohm loop fed into a 2 ohm RX.

If I do not buffer the loop from the RX, wouldn't a 2K loop fed into a 2K RX also cause similar loss of Q (just like the 2 ohm over 2 ohm example you gave previously)?

I'm absolutely sure I'm not out of the woods yet, but does it look like I'm on the right road yet?? It's a big change for me, can you give me a brief indication please....

Thanks.

And, I am definitely not avoiding the I/Q issue. I know of successful hardware handling examples of the I/Q and also of successful software handling methods. I just haven't decided which one to use yet. The stand alone hardware is a bit harder to implement, complex filters, much more hardware to build, and a wideband phase shifting network are needed. But the advantage is that it's a stand alone solution.

Software works well also, but leaves one dependent on the programmer and requires a computer. Not sure which way I'll go, but it's not important yet as I don't have a viable front end and antenna yet.

So, am I on the right road, or am I still very far off track with regard to the antenna Q issue?

Regards,

T

Dear Trabem,

The input impedance seen looking into the series-connected loop is the RF loss resistance of the loop, in your case about .05 ohms.

If 0.05 is impedance-matched to a 10-ohm receiver then the working Q only falls to about 100. But it is not an easy matter to match 0.05 ohms to 10 ohms at 60 KHz. (I do not know the precise input resistance of your receiver but you get the idea.)

The working Q of any tuned circuit, either series or parallel connected, when impedance-matched to a load, always results in the working Q becoming equal to half of the tuned circuit's intrinsic Q.

This is rather obvious because the loss resistance of the tuned circuit and the load (after being transformed to the tuned circuit value) are equal to each other.

Of course, impedance-matching also results in maximum voltage and maximum current being developed in a given load (or receiver). Which is also a desirable condition.

It is a serious mistake to think in terms only of volts-input to the receiver. Or only current-input to the receiver. Receiver S-meters are POWER meters. That's why they can be calibrated in decibels or in terms of 6dB per S-unit. Or S9 plus so many decibels.

For example, with a 50-ohm receiver, the reference level S9 = 50 pico-watts receiver input power.

Please accept my apologies for digressiing from 5-metre square loops at 60 KHz.

Reg.

The advantage of Q is that it multiplies I and V giving you
sensitivity. As I have pointed out before, your current design could
work without any changes. I cannot answer this for myself much less
you and the advice I would have to offer is that you build your
receiver with flexibility in mind. We are not talking big changes in
components. That is the long answer. The short answer is yes.

>If this is the case, an active buffer amp seems inevitable.

Easy enough to include, or remove depending on need.

>If I do not buffer the loop from the RX, wouldn't a 2K loop fed into a
>2K RX also cause similar loss of Q (just like the 2 ohm over 2 ohm
>example you gave previously)?

Certainly, but not similarly. The Q is not going to plunge to 2 or 3.

>And, I am definitely not avoiding the I/Q issue. I know of successful
>hardware handling examples of the I/Q and also of successful software
>handling methods. I just haven't decided which one to use yet.

That is the point of my questions. They are veiled implications, not
tests of knowledge. No one in your list of links, much less those
I've read over the years knows the PRACTICAL implication of the "I"
and "Q" channels. So, I may as well drop the other shoe.

One does the demodulation of AM signals, the other provides
demodulation of FM and SSB signals. I'm not sure which and what
particular arrangement of supporting circuitry is required beyond
simple AM amplifiers because my construction for that application was
back in 68-69. Building tube models and guaranteeing design
considerations was not as simple as the Tayloe circuit offers now.

However, one of the fascinating characteristics of this style of
detector is that you can feed each channel to the earpieces of a
stereo headset. "I" for one, "Q" for the other earpiece. This gives
you the chance to use your wet-ware instead of someone's software and
hardware.

The brain does all the necessary fourier analysis automatically and in
real time. The upshot of it is that when listening to a CW signal,
and hearing the field of signals around it, you perceive those signals
in a mind-space. The signal that is center tuned sounds like it is

between your ears, in the middle of your, as I described it, mind-space. Those signals that are above it in frequency sound as though they are coming from the right, and those signals that are below it in frequency sound as though they are coming from the left.

The advantage of this detector, in this configuration, with this kind of perception, is that your mind is separating the signals psychologically. Even though the signals you hear on the left and right are in equal amplitude to the center, you can exclude them mentally. Imagine taping a conversation in room full of people and the microphone is not at your, or your partners lips, but between you, and you are both standing off a couple of feet talking over the crowd. You full know that you could understand your partner at the time of the recording, and you probably know that the tape would be a bitch to make sense of, even though it makes a faithful record of the conversation in that free-for-all.

The difference is that your binaural perception with its phase separation capability could be brought to bear to ignore the field of noise to concentrate on your partner. When you hear the mono recording, the phase information is lost and your partner's conversation merges with the background noise.

I cannot personally vouch for this effect because the payoff in my construction back then didn't come down to finally evidencing this effect for myself. This wet-ware characteristic was reported to me to be one of the attractions of building for my professor. I have also played with bucket-brigade delay lines to create this effect. At one time Paul McCartney was using it with his music. Aural phase relationships have a strong psychological information content that is taken for granted.

The mixed-up confusion along this extended thread is due to the inability of contributors to describe in plain English exactly what they mean about a relatively simple matter. It's a breeding ground for baffle-gab, confusing nonsense and old wives.

To avoid wasting more time I respectfully suggest Trabem obtains a big bunch of capacitors of various values and gets on with the job. We will all be very interested in the outcome.

Now perhaps we can return to which part of a 1/2-wave dipole does the most radiating - the middle bit or the ends?

Reg, G4FGQ.

OK, maybe you're beginning to understand. Q can be calculated as reactance (at resonance) divided by the effective series resistance, or as effective parallel resistance divided by reactance at resonance. For a loop where you know the series resistance, it's easiest to use that first relationship. If you put your 10 ohm receiver input in series with your 10 ohm reactance loop, you've ruined all that effort to get to a very low loop conductor resistance and obviated the need for high-Q capacitors. And we're all having a very hard time seeing how you will couple your 10-ohm receiver input to EITHER the parallel-tuned loop OR the series tuned loop, without having nasty consequences for your holy-grail Q.

You might think it's best to impedance match ("conjugate match") to your load, so you transfer the most power to the load. However, that may not be optimum from a system design standpoint. If you already have enough signal (along with atmospheric noise) that the receiver doesn't contribute significantly to the overall SNR, then you may be better off by intentionally mismatching so that the Q remains high, if that's important to you. (I personally think you've overrated it, but that's up to you to decide.) But even if you're wanting to get the lowest noise contribution from your electronics, the appropriate match is generally not the conjugate impedance match that results in highest power transfer. For example, an MMBT2222 NPN transistor running at about 100uA collector current in a common-emitter configuration with no feedback will have a low-frequency (e.g. 60kHz) input resistance around 50kohms, but the optimal source resistance from a noise standpoint--the source resistance which will yield the lowest noise figure for the amplifier--will be about 2kohms. At optimal source resistance, you can get a noise figure well below 1dB from an MMBT2222--and from many other bipolars.

One reason that people like to use FET amplifiers across their "parallel-tuned" loops is that the amplifier input resistance is quite high, but (using appropriate FETs) the noise contribution of the amplifier is negligible. And with proper design, the distortion contribution can be considerably lower than the distortion of your detector. For high source impedances, JFETs can give noise figures that are a small fraction of a dB.

Cheers,
Tom

OK Reg,

Hi Reg,

Read both of you responses, and it's very clear now that I was seriously out in a fantasy world with respect to the topic. I feel a lot closer to reality now.

If you can, check the latest comments between Richard and myself. I think I'm getting it, or at least the first approximation:>:

You provided a key piece of info when you gave me the verbiage about the loaded Q formula in a series tuned loop. When I started out, I had no idea that the loaded Q could possibly drop so much when connected to a receiver!

>The working Q of any tuned circuit, either series or parallel
>connected, when impedance-matched to a load, always results in the
>working Q becoming equal to half of the tuned circuit's intrinsic Q.

I knew this already!

My big problem was in realizing that the loop impedance was so very very low. Once Richard got me a closer approximation of the actual number, it became VERY clear to me that there was no impedance match in my original configuration! Richard suggested the impedance of the loop was 2K, I guessed it was 2 ohms, but the actual figure was in the milliohm range.

I feel SO MUCH better now and I think I'm much better off thanks to your (and Richard's) patience. Thank you so much for helping me to get to this point!

T

This should require a matching transformer otherwise not enough current can flow to take advantage of the potentially huge Q. Without current flow there will be no energy storage in a series circuit. In a parallel circuit the current flow is internal between the parallel reactances but in a series circuit it must be external. A series circuit is naturally current driven so the transformer would basically be converting current into a voltage that the receiver input can use. If you measure your loop with a test signal you should find it requires a lot of current and little voltage. From your investigations, calculate the effective resistance and use this as your Rs to find the actual Q and the matching turns ratio required for an autotransformer, for example.

Good luck,

A*s*i*m*o*v

Hi Richard,

I feel SO MUCH better now!!!!!!!!

Just read and replied to Reg's latest comments a few minutes ago and it seems I am on the right track-my major error was not realizing that my series loop impedance as originally suggested was very much lower than I thought it to be ...and I've finally realized that it COULD NOT POSSIBLY be matched to a receiver that had 2 (or 10) ohms input Z.

Now that I've realized my originals series loop antenna had an impedance in the milliohm region, the other explanations that you gave made perfect sense.

At least, I feel like I made it to the first level:>:

I'm a little hesitant to make this suggestion, but let me ask the question(s) at the risk of taking to large a step forward and stumbeling:>:

If you would, just give me a yes or no answer to these questions so I can make sure I don't have seriously flawed remnants of the old thinking.....

With the current model of parallel loop...

If my receiver was 2K input impedance (whether tuned input or not), could I connect it to my loop with a piece of 2000 ohm open wire line and expect the net (or loaded) Q to be around 100 (assuming a 2K impedance open wire line could be built and that my unloaded antenna Q was 200 to start with).

Yes or No?

With the current model of parallel loop...

If I elected to use a buffer amp with megohms of input impedance, would I preserve the unloaded Q and end up with a net Q of about 200 because I haven't loaded the loop?

Yes or No?

I believe my receiver is microvolt sensitive and that the loop will deliver a relatively good signal to the receiver even though the loop isn't terribly efficient. If I build selectivity into the front end of the receiver, do I really need high Q (200)??

I think the answer is NO.....

Since my receiver is quite sensitive (characterized at uV before I convert it to VLF), I think I could save a lot of money by sacrificing some antenna Q and building modest selectivity into the front end.

Or, I could elect to use the antenna as planned (impedance matched, but no front end tuned circuit) and instead convert the receiver to an untuned input (allowing the antenna Q to be the sole form of tuning).

Is this reasoning basically correct or seriously flawed?

>
>However, one of the fascinating characteristics of this style of

>
>The brain does all the necessary fourier analysis automatically and in
>real time. The upshot of it is that when listening to a CW signal,
>and hearing the field of signals around it, you perceive those signals
>in a mind-space.

OK, I am an avid cw operator, often operating as a hired gun at m/m HF contest efforts. So, I completely understand the concept of having the brain do the processing. The brain is a very seriously viable filter that is adaptive with regard to the audio spectrum sent to it by a conventional receiver.

I haven't tried actual binaural operation, but have heard others talk about it. The users claim it is a different world from the very first second of listening to it and are constantly amazed at the effect and improvement.

I have a friend who isn't quite local...but we chat from time to time although we don't see each other that often. He has a high frequency hearing loss in one ear and has a great deal of difficulty with cw. He built a binaural project from a QST article and was stunned to hear the results. He was sold ont he idea in short order!

But I never though much about hooking up a stereo headphone to the i/q audio streams.

>The difference is that your binaural perception with its phase
>separation capability could be brought to bear to ignore the field of
>noise to concentrate on your partner. When you hear the mono
>recording, the phase information is lost and your partner's

>conversation merges with the background noise.
>

OK, I am with you with respect to the brain filtering out unwanted conversations to let you focus on your conversational partners distant voice. But, I thought traditional binaural receiver meant that the frequencies higher than a certain point went to one ear and that the all the frequencies lower than the same frequency went to the other ear. In this manner the listener has a feeling of 'depth' or 'richness' that isn't present in a mono setup.

This is interesting though.

But, I never thought that the brain could process the I and Q to provide opposite (unwanted) sideband rejection...which is why I thought the primary function of the I/Q precessing was about (whether it be hardware or software based).

Are you suggesting that the brain can also process the I/Q output streams and provide opposite sideband rejection as well as selective frequency and adaptive filtering?

>I have also
>played with bucket-brigade delay lines to create this effect. At one
>time Paul McCartney was using it with his music. Aural phase
>relationships have a strong psychological information content that is

Trabem,

Without wishing to detract you in any way from your objective of a matched series tuned loop I would like to describe how I would do a similar job with the usual parallel tuned, multiturn loop.

I do not understand the type of receiver you propose and I am not seriously interested. But I should say the theoretical working bandwidth of my proposal is about 1/2 of yours.

Actual bandwidth of both your and my proposals is indeterminate because of the uncertainty of ground proximity and nearby environmental loss. The working bandwidths could be very similar.

Using similar size loop dimensions to yours, ie., 5.3 metres square -
Frequency = 60 Khz.
5 turns of close wound 2mm diameter enamelled wire.
Inductance = 710 micro-henrys.
Tuning capacitor = 0.01 uF approx.
Reactance of L and C = 268 ohms.
Conductor resistance loss = 2.5 ohms.
Intrinsic coil Q = 107
Matched working Q =53
3dB working bandwidth = 1.12 KHz.

Impedance match to 50-ohm receiver obtained via small coupling loop, in the same plane, about 1 metre square. Working Q = 53 or less depending on height above ground.

The working Q may not be high enough for your particular application. I describe the antenna for you to see what is possible in comparison with your series-tuned proposals.

Reg, G4FGQ.

I have a VW Jetta with the "shorty" antenna. I am pleasantly impressed that it works better than the long steel type. The active (electronic) antenna is superior, and I get reception when no one else can.

Here is my question for the techys:

I am looking at getting an Avanti. The shorty antenna would look very rakish, and a nice replacement for that stock extended steel. The body on the Avanti is Fiberglass.

1. Do you ground back to the frame?
2. I suspect that the shorty antenna uses the metal roof as a ground plane, true?
3. If true, what is the implications for using the shorty, active antenna on the fiberglass?
4. What are the different model names/numbers for such an antenna, and what is YOUR OPINION of each?

URLs appreciated

thanks!
terry

Didn't Don Stoner describe a synchronous detector way back. I think I
remember reading an article in the mid sixties in "The Sideband
Handbook" or similar.

I was about 15 then, so a detector that had something like 17 bottles
in it seemed overkill when I was copying CW and SSB on an AM receiver
(ie diode detector) with BFO.

The appeal being an all-mode detector (including DSBSC), but
synchrounous detectors didn't seem to catch on in comms receivers,
well not until DSP detection... well I don't recall coming across them
anyway.

You need to run a ground strap to the frame, but the lower mounting on
the Avanti's rear fender may hurt reception a bit as well as the poorer
ground plane.

I don't know the answer to your question, but I can tell you this

a) the VW antenna has a star washer under its mounting nut, so your assumption that it is grounded to the car body may be correct. If that is the case you will need to probably solder a lead to a large flat washer to replicate that setup.

b) the manufacturer of said antenna is "Fuba" which might help you in your search for information.

Personally, I haven't had much luck with Fubas, every car I've had that is so equipped has had zippy AM reception, as the amplifier section is already blown by the time I acquire the car. (I tend to buy my daily driver type vehicles fully depreciated.) Also, shit you not, squirrels apparently like to gnaw on them. Dunno if that's of concern to you or not, but replacement masts are available and just screw in. (take them off before going through a car wash, too...)

If you do choose to go forward with this and are looking for economical sources, I'd look to the VW aftermarket, such as parts4vws.com or similar.

Another thought would be to use the trunk mount antenna from a GT Hawk, it looks very Fuba-like but is "period correct." I don't know if there is any way you could rig Fuba guts to work with the Stude trunk mount unit, but if it could be worked out I might consider doing that for my '55 coupe.

Finally, I've even seen fender-mount Fubas; I know they were used on A3 cabrios. Might be able to adapt one to work in the stock location rather than having to drill a hole in the roof (yikes!) to mount the angled-back style.

You may also want to post to rec.autos.makers.vw.watercooled or to the Vortex...

good luck,

nate

You have too many suppositions to give a straight answer. First,
there is no such thing as a 2000 Ohm open wire line. As for the gist
of the question:
Yes.

>With the current model of parallel loop...
>
>If I elected to use a buffer amp with megohms of input impedance,
>would I preserve the unloaded Q and end up with a net Q of about 200
>because I haven't loaded the loop?

>Yes or No?

Yes.

However, as Tom has pointed out separately, this may not be the
optimal solution.

>I believe my receiver is microvolt sensitive and that the loop will
>deliver a relatively good signal to the receiver even though the loop
>isn't terribly efficient. If I build selectivity into the front end of
>the receiver, do I really need high Q (200)??
>
>I think the answer is NO.....

Well, this is a good opportunity to examine that tumble down the slope
to the Q = 2 (caused by the severe loading of your proposed design).

The correlative to this is, how much selectivity do you need in a
field where stateside VLF is relatively rare? Further, by the action
of the strong filtering that usual attends the "I" and "Q" channel
processing, you could easily repair any shortfall.

However, back to that Q = 2. That still offers respectable (not
fantastic) selectivity against signals out at the bottom of the AM
band which is 10f (one decade) away.

>OK, I am with you with respect to the brain filtering out unwanted

Binaural is what the fellows in white coats mean by listening with two
ears.

>This is interesting though.

And rarely reported for this style of detection. What a pity.

>Are you suggesting that the brain can also process the I/Q output
>streams and provide opposite sideband rejection as well as selective
>frequency and adaptive filtering?

The rejection is psychological, not actual. It is what I meant by
"mind-space." The vectors do not add up to zero, the mind simply
ignores the off-band content like you would at a party listening to
that cute office temp's whispers when your wife is yelling across the
room at you.

Listen to a recording of that same scenario in mono and you WILL hear
your wife!

The brain reassembles all delay/phase information content at the party
to sort out what to pay attention to. When that same information is
passed through a monaural channel, the phase information is lost and
everything competes equally lousy given the S/N ratio.

Assume an incoming rf signal has exactly the same strength in all 3 dimensions i.e., completely omnidirectional. Question: would an antenna having gain capture any more signal power than a completely omnidirectional antenna with no gain?

It appears to me that a 10 ohm receiver input impedance is dead center
with regard to any loop configuration I could come up with...it
doesn't work with anything! It's easy to see now:>:

>You might think it's best to impedance match ("conjugate match") to

>

Is the MMBT2222 the same as a 2N2222, which I already have in my junk
box? Also have 3904's, maybe they are just as suitable?

Should I tune the output, or rely on a modest input tuned filter in
the front end and just do a no tune in and out common emitter?

Assuming a 50 ohm receiver input impedance, is it ok to take the
output across a 50 ohm emitter resistor?

>One reason that people like to use FET amplifiers across their

JFET's sound good too.

Richard, which type of buffer amp has a lower distortion and better
linearity in the presence of (potentially) large out of band signals?
If I do use a buffer to preserve the Q, it has to be 'clean' in order
to preserve the performance of the QSD receiver. Appreciate any
enlightenment along these lines.

I'm not opposed to using an op amp IF it provides cleaner output
signals and if the power consumption is manageable.

I must say it seems much cheaper (and probably more practical) to use
a buffer to preserve the existing Q than it is to build higher Q into
the loop...only to have it cut in half by the addition of a receiver
front end.

Hi Owen,

17 bottles indeed. That seems to strike a resonant chord in the ganglia because my construction was on a utility box of about 3" x 9" x 15" (not counting power supply requirements). We were working from a printed article certainly; and to confirm your recollection, there was a list of modes that could be detected that was long.

My perception of the resurgence of interest in synchronous detection (it seems to have many names) is that a considerable body of knowledge evaporated in the 70s and 80s to leave only fragments of what this detector was useful at.

I understand the Bell Labs explored this effect (which they referred
to as the "cocktail party effect") when exploring the nature of
conversation for the purposes of novel approaches to telephony
multiplexing.

I don't think they developed a technology solution to exploit the
cocktail party effect, but they did incorporate their knowledge of the
statistical / syllabic / sentence characteristics in their Time
Assignment Speech Interpolation (TASI) equipments, and TASI was quite
successful.

I think the term we would use for the cocktail party effect on a phone
channel is "a crossed line", and you may be right in that the loss of
spatial information because of the mono channel may have been the
reason it didn't work.

Hi Owen,

This mimics Paul McCartney's use of phase mixing in his music in the late 70s. Earlier, I was using Reticon bucket-brigade chips to develop a frequency independent delay line such that I could mix input and output (much like the FIR/IIR topology of today's DSP technology, except I was doing it in analog rather than digital) to obtain a variable phase. I still have the breadbox sitting on the shelf. I was anticipating using this device to place "voices" in the stereo-space of program content that I was mixing for. The concept was much too cerebral for the producer who simply wanted matched levels.

Whatever the net field that arrives from the transmit antenna (whether or not the transmit antenna is omnidirectional), a receiving antenna having gain in the direction toward the transmit antenna will perform better than if it is omnidirectional.

Part of the improvement is due to its added gain, and part due to interference rejection from co- and adjacent-channel signals arriving from directions where the receiving antenna has less gain than an omni antenna.

Your scenario is a little confusing.

Here are my thoughts:

I we took the case of say, noise that was sourced from all around you (that is not to mean an isotropic transmitter antenna), a directional antenna would receive about the same power as an isotropic antenna, and the difference would be due to antenna losses, ground reflection losses (if relevant).

Galactic noise on HF might nearly fit into that scenario (or perhaps more topically, neighbourhood BPL interference), and I would expect that a 8dB yagi would receive similar power to a half wave dipole. Galactic noise is a little lower at the galactic poles, so in sweeping the yagi you may observe a very small directional effect. Further, ground reflection and different antenna + feed losses will introduce small differences.

If at the end of that, you are trying to rationalise why a beam is better than a dipole, although the beam does not receive more or less of the "directionless" noise, it does increase the receive power from noise, interference and signal from the main beam direction and reduce receive power from noise and interference from away from the main beam.

Does that hang together?

Owen

OK, I'm not sure how we got back to the Q=2 scenario. I think my
proposed design is the old series tuned loop, which I have firmly
rejected.

With no tuning in the front end, the Q of the receiver would approach
1.......Yes, I understand that.

I understand the answer you gave initially, which was 'I think the
answer is NO....'.

I understand the degree of protection against signals in the bottom of
the bc band.

When you said "Well, this is a good opportunity to examine
that tumble down the slope to the Q = 2 (caused by the severe
loading of your proposed design)".....................did you mean
to say or to infer '(caused by the severe loading of your old (now
defunct) series resonant loop design"???

All is in agreement above EXCEPT in not sure why the reference to the
old design.

Thanks again.

Concerning #1, 2 and 3:
Chances are it needs a ground plane of some sort around it. You could
make a ground plane for it by using self sticking copper foil on the
inside of the fiberglass panel the antenna is mounted on. The foil
should extend some distance from the edge of the mounting hole for the
antenna in all directions and then use a metal washer inside the panel
to mount the antenna with, which will make contact with foil.

Hi Terry

I find it difficult to think of the whip for AM radio reception on a car
as 'the antenna'. It is more like a probe of the currents flowing on the
outer surface of the car. The "shortys" on cars with amplifiers mounted
at their base certainly arent antennas.
A plastic car provides the Shorty with an environment thats considerably
different from that anticipated by the original Shorty design.
A strap to the chassis might be a solution for installing a VW amplified
antenna. But,would you consider a radio intended for a Corvette??

Jerry

Yes.

The amount of signal "captured" from a given direction is exactly proportional to the gain in that direction. "Capture area", "effective aperture" and "gain" are simply different ways of expressing the same thing, as long as perfect efficiency is assumed; if you know any one you know the other two.

Yes
of course.

You have asked a number of questions outside of this old (now
defunct) design, but you haven't, as far as I can tell, formalized a
replacement.

The ancillary point that I've made is that the original could work.
However, you've never stated any operating specification to test that
against. I've offered that all components need to be scrutinized in
the face of your goal. We saw where that lead.

You've only specified your desire for High Q capacitors (properly, low
D capacitors). I offered that ESRs vary widely and could easily
derail your goal. The presence of an ESR equal to the 0.06 Ohm of the
loop is very well within being guaranteed. It still is. Reg
dismissed this as inconsequential. So be it, but being that it is
easily remedied through selection, then why toss away half your Q to
casual indifference?

What Reg actually meant, and he has a hard time with that given he can
often be found on both sides of an argument, is that such loss may not
matter. There I agree, but this does not advance the topic of High Q
Caps for VLF Loop Antenna when they can be obtained.

Maybe I should restate my question. Assume a receiving antenna is in the center of a sphere and the received signal is coming in equal amounts from all points on the surface of the sphere. Which receiving antenna would capture more power, an omni or a high gain beam? There are no noise and no losses.

Agreed!

Just wanted to be sure I didn't miss something, so I asked.

And, your're right, I haven't formulated a replacement. I bought a 250 foot poll of cable, and it has not been cut. So, it's still in one piece and returnable if I decide not to use it.

I was just pondering the alternative of allowing the front end to be untuned. The receiver is susceptible to harmonics, each harmonic of the tuned frequency is down 6 db though. Since the loop would be resonant somewhere on HF, it is probably a bad idea to leave the front end untuned as HF can be unpredictable. so, I am thinking I need some front end selectivity.

Reg gave me an example of what he might do. And his antenna came out much cheaper to build and probably easier to put up.

I'm also thinking about the method of feeding the signal to the house. It will be around 70 feet from the house, so 90 feet of cable of some sort is needed. I can easily go 700 feet in any of 3 directions, but there is probably no practical need to go that far out into the woods. Since the house is a noisy place for LF and VLF, I have to be concerned about how I feed the antenna. I also think I'd like to have it fed with balanced line to minimize the possibility of the feed line acting as an antenna. If a preamp is used, I have to feed power to the antenna as well, so I will have to wind a common mode filter to do that job as well. So, I got a lot to think about.

Although I haven't formulated a plan for a replacement antenna, the series loop is 99.99 percent history.

So, I am thinking about it.

I have a reading session planned for the late night here so I can reinforce the lesson(s) you and Reg have taught me. And, will probably work on the actual antenna design tomorrow. My caps are on order from Mouser, should be here next week

There are a few preamp designs around the web, but none of them seems very well thought out...although they might be well planned. It's possible they are solidly designed, but that the authors haven't shared all the gory details in their web presentation(s).

Thanks again. I'll keep you posted if you like.....I'd appreciate sending up a red flag if I attempt to commit additional acts of stupidity with regard to whatever I come up with for a design.

Regards,

T

An isotropic antenna would be the best, as the field described came
from the same emitter (such a field would be impossible otherwise).
Stepping out of this enigma (that the emitter and detector are
different, and the field which could only be generated by an isotropic
would then suddenly turn and come back) would answer the omni.

To emphasize one idea that Richard Clark has presented:

Here is a direct quote from page 6-1 (section 6.2) of the chapter on loop antennas in the (first edition) Antenna Engineering Handbook edited by Jasik (1961):

"The radiation pattern of a small loop is identical with that of a small dipole oriented normal to the plane of the loop with the E and H fields interchanged."

The use of "magnetic" or other buzz words notwithstanding, a small loop is the dual of a small dipole. Practical considerations might cause one to select a small loop over a small dipole.

Are you trying to receive the background radiation left over
from the big bang? That's the only source outside of the
sphere that I know of that can accomplish your boundary
condition.

> considering smaller diameter multiturn loops.
>
==========

With multi-turn loops don't be tempted to neglect wire diameter.

And it's well worth while spacing the wires by 1 or 2 wire diameters.
Spaced wires reduce RF proximity-effect loss and increase Q.

Neatness of construction is of little consequence. Wires need be
supported only at the corners of the loop. Keep wires taut enough to
prevent them flopping about in the wind.

Electrically isolate the main loop. Don't connect it to anything. It
will then maintain its good directional properties including its sharp
null.

Don't even think about screening or shielding the loop. It will serve
no useful electrical purpose. It will cause proximity effect to
reappear.

Connect the smaller coupling loop to the unbalanced receiver via a
thin twisted pair of whatever length you like without fear of it
picking up any signal of consequence.

Remember sensitivity depends ONLY on the enclosed loop area and NOT on
the number of turns. So don't be tempted to reduce loop size just
because it is multi-turned. Big signals never did anybody any harm.
Whereas . . . . . !

I assume your QTH is not adjacent to WWV's antenna. ;o)

They'll intercept equal amounts, assuming both are lossless. The directional antenna will intercept a larger fraction than the isotropic antenna in the directions it favors, and less in others. The total will be be the same.

In reverse, this is equivalent to calculating the average gain of the antennas, which is the same for all lossless antennas.

You only need a ground plane if the aerial transmits - for a receive
only you can kust mount it, end of story.

It is NOT a good idea to connect an earth bond at the aerial end as
the aerial cable and that bond might provide a lower resistance feed
to other vehicle electrics than the designed route and end up causing
severe interference.

Not true, here's a GM service letter about the fiberglass bodied Vette:

"Antenna Ground Plane Upgrade

GM issued a service bulletin for an improvement to the radio antenna. It
can enhance the quality of FM radio reception. This is applicable for
ï¿½90 through ï¿½91 Corvettes. Some customers have been very impressed with
the results. The results are dependent on the quality your local radio
signals and the quality of the installation. High quality installations
are performed only if the installation is exactly as specified by the
technical bulletin. The improvement was incorporated into factory
production in the ï¿½92 model year.

The method is to create a ground plane for the antenna. Four wires that
are ï¿½ wavelength long join together to form an electrical ground field
at radio frequencies. The C4 Corvette has a narrow steel band located
under the antenna. It is designed to function as a ground plane, but its
area is too small for optimal performance. Other cars donï¿½t have this
difficulty because metal exterior panels provide the ground plane."

Another excellent tarnish-remover for copper, brass, and silver can be made from baking soda and ammonia water, both available from any decent supermarket. Takes off the tarnished surface almost instantly, leaving clean bare metal, and rinses clean with water.

Ron, W4TQT wrote:
"Question: would an antenna having gain capture any more signal than a completely omnidirectional antenna with no gain?"

Directive gain depends entirely on the distribution of radiated power. See 1955 Terman page 870. The antenna gain figure is identical for transmitting or receiving. To take full advantage of gain in a line of sight path, the electric vector must be parallel with that received. Cross polarization can cause up to almost 30 dB signal loss. There are directional antennas that receive vertical and horizontal polarizations equally well.

Yes. An antenna with gain captures more signal than an antenna with no gain when both are in their best positions and equally distant fron the same signal source.

Best regards, Richard Harrison, KB5WZI

I guess unless both stations were using a helical antenna, an array of yagies would be better. Since the helical antennas would have to have opposite polarization, that would be pretty inconvenient unless both stations had an array of RH for TX and LH for RX, in which case you would have to build twice as many antennas.

I did have an idea for mounting them though. I was going to find something to use as a form to wrap the helix around and then cover it with fiberglass, making a big fiberglass tube, then remove the mold from the inside. I think that would make for a pretty strong and lite structure. I would then make some kind of fiberglass structure to mount the antenna at it's CG. Of course such an antenna would have a pretty high wind load, so you would need a way to easily take it down in case of high winds.

2899. Re: HIGH Q CAPS FOR VLF LOOP ANTENNA?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-29 17:18:09 UTC
From: TRABEM <>
Message-ID: <6ab7m1hulck0nf2oomgbc5gbv07n4j8lis@4ax.com>
Source record: 68296

Hi REg,

Looks like I have a plan for a new loop.

New loop design:

I have a plan for a more appropriately dimensioned loop.

At 60 KHz,

4 turns of 2 mm diameter wire, spaced 4 wire diameters apart.
2 meters per side
123 uH, 60,000 pF to resonate
4.7K across the loop.
300 ohm feed impedance at single turn loop feed
Q (unloaded) = 101

This allows me to feed the loop with 300 ohm balanced line, which I
can easily transform to 50 ohms at the receiver.

I'm not sure what the impedance of twisted wire is though, which would
be even cheaper than 300 ohm twin lead.

Also, my Q will be slightly higher as I can stagger the turns some, so
that the wires won't run parallel to each other for the entire length.

I was never quite thrilled with a big loop threaded through the trees
and supported in that manner, it makes it hard to rotate:>: Being able
to rotate the loop is a good thing:>:

Is the 1 turn pick up loop critical???

And, I have another question.......

I used rj2loop3 and ran the same numbers as above, except that I
separated the wires by 10 wire diameters instead of 4.

Instead of seeing the Q improve, it was reduced (from 101) to 93. I
expected the Q to improve, not get worse. It seems odd to me. Is there
a good reason for this?? Ran it with a very low number and the Q also
get worse. So there appears to be an 'optimal' wire winding pitch for
optimizing Q?

Byr the way, nice software package, thank you for it's use!

>I assume your QTH is not adjacent to WWV's antenna. ;o)

Temporarily, it is on the East Coast of the US. But, at home it is
high in the mountains in Northern EU (with no commercial power for

miles around).

Thanks,

T

Hi Chris,
You're right on the polarity sense- it gets reversed upon lunar surface
reflection. At 23cM we are using a scalar or septum horns that have 2
feedpoints- CW and CCW- much easier to to do with a horn as it only involves
a 2nd orthogonal probe. A set of 4 capacity stubs arranged longitudinally
along the guide generates the 2 senses.
If you are seriously interested in EME- take alook at 23cM. Gain is easy to
come by in the form of dishes; LNA NF are now in the <0.2dB and power from
the GS series tubes and Mistubishi modules are stable and quite easy. Not
unusual to hear SSB stations ragchewing on activity or contest weekends, no
Faraday issues and lots of big gun activity.

Trabem,

I will try to answer your remaining questions in the order at which they occur.

There must be a compromise between size of loop, receiving sensitivity, and the ability to rotate it. Only you can decide. I can suggest only that you bias your opinion towards size matters more than the ability to rotate the thing. Just make sure that the broadside null does not correspond to the direction from which your favourite transmissions come from. The receiving lobes in the polar diagram are very broad. The polar diagram is a figure of 8, like a pair of touching circles. You won't need Eznec.

The impedance of the line from the coupling loop to the receiver doesn't matter two hoots. At 60 KHz it is just a pair of wires. A twisted pair of wires has an impedance of very roughly 130 ohms. But at 60 KHz the line length is so short in terms of wavelengths it doesn't matter what its impedance is. The coupling loop can be considered to be directly connected to the 50-ohm receiver.

And even with an extremely long line any impedance mismatch loss will be negligible. So forget about 300-ohm balanced line and just use a simple not-tightly-twisted pair. NO IMPEDANCE MATCHING REQUIRED at either end. The size of the small coupling loop inside the main loop matches 50 ohms to a 50-ohm receiver. So ideally the line to the receiver could be 50-ohm coax. But, as I say, it doesn't matter.

The size and shape of the small coupling loop is not critical. It can be circular or square. Theoretically, to match the loop to a 50-ohm receiver, it should have an area about 1/25th of the main loop area. To simplify construction the coupling loop can be made self-supporting.

Electrically, the thickness of the wire in the coupling loop need be no greater than the wire in the line which connects it to the receiver. The only wire diameter which matters is that of the main loop itself.

As the spacing between wires on the main loop increases the RF proximity loss in the loop conductor (related to skin effect) decreases and Q increases. But other things happen when the width of the loop increases with spacing. For example, loop inductance decreases. We are not comparing like with like. And in any case maximisation of Q is not the primary objective. There are other things to be considered.

For example, if you want to increase Q then don't bother to increase spacing between turns, just increase wire diameter.

But with given wire diameter, the optimum spacing between the wire centres of adjacent turns, to maximise Q, is very crudely about twice the wire diameter. But, as I say, it is very non-critical and you might be better off by increasing wire diameter as it simplifies loop construction. Then, once again, you will have the option of increasing spacing between turns. Compromises are never ending. ;o)

Whatever you end up with I can see from your enthusiasm you are enjoying your efforts and will continue to do so.

Reg, G4FGQ.

Somehow I think what industry has in mind are ways to tap into "unused
spectrum space" dynamically and exploit it for Internet access
services. You don't need to look very far into their proposed method
of operation to see that a squat on a frequency band soon makes it
unused by anyone else.

Aren't the IEEE working on standards for such spectrum exploitation?

These ideas share a bit in common with the BPL menace, uncoordinated
access to spectrum, and put the onus on the licenced service subject
to interference to follow a regulatory maze to regain access to their
licence entitlements.

Owen

PS: "unused spectrum space" means not licenced to the squatter, and
not carrying enduring signals sufficient in strength to interfere with
their squat.

Here's a related question that may help you answer yours:

Do all (assume lossless) antennas with the SAME directionality caputre
the same signal power?

If the answer to that one is "no," then I think you must first further
qualify your question, or it will be like comparing canteloupes and
grapes.

Cheers,
Tom

I think the appeal of it in the early days of suppressed carrier
exploitation by amateurs lay in its application to DSBSC demodulation.

It probably fell by the wayside when filter method SSB transceivers
became lower in cost.

Here is an interesting hypothetical. Australian amateurs at the
unrestricted licence grade are subject to the following power
restrictions:

16 Transmitter output power
(1) Subject to section 15, the licensee must not operate an amateur
unrestricted station, using a transmitter output power of more than
400 watts pX, if the emission mode of the station includes:
(a) C3F; or

(b) J3E; or
(c) R3E.
(2) The licensee must not operate an amateur unrestricted station, with an emission mode not mentioned in subsection (1), using a transmitter output power of more than 120 watts pY.

Since the emission mode for DSBSC is not one of those mentioned in 16(1), then the power limit is 120W pY. If the pX/pY (PEP/Average) power ratio for radiotelephony is somewhere around 12dB to 15dB, that suggests that (using a worst case of 15dB) that the 120W pY DSBSC telephony transmitter is around 3800W pX (PEP), whereas you will note that if we use SSBSC (J3E) we are limited to 400W pX.

Doesn't make sense, does it. Did I get the maths wrong?

Hi Owen,

Gad! I left all that computation behind when I finished the exam for FCC 1st Class. (Actually when I finished the Radar portion as I took the entire suite of tests, 3rd, 2nd, 1st, and Radar endorsement in one sitting.)

However, I do recognize a strategy when I see it, and I doubt, beyond slipping a decimal the wrong direction, you may have found a loophole.

I'm trying to shoot a line over a tree limb to hoist my next generation of wire dipole.

I'm using a slingshot, a 1 oz round lead fishing weight, and in this case, 40# test fishing line.

Although I have had fair success in the past, I'm having difficulties lately. My weight won't pull the line down the other side of the limb beyond where it stopped.

My Question: What weight do you guys recommend? Does anyone know what weight is used on the EZhang system? Comments sollicited.

Right now I'm waiting for the wind to blow and hopefully move the tree limb enough to make the hanging weight pull my live over to the point where I can reach it.

Using an Icom 746 Pro here which includes HF/6M/2M with a full 100W on all bands. I have been on HF since 1995 and an avid DX'r and secretly sneered at VHF/UHF but did want to try 2M SSB.

I now have VHF antennas at 72' 90' and 95' and am net control and founder of the Deep South 2 Meter SSB Net.
There was very little 2M SSB traffic in my region when I got on 2M SSB but since the net started on April 8, 2005 we have now had over 100 2M SSB stations check-in representing 10 states so far.

Typically there are 25-35 or more O(record is 39) check-ins every evening. So..for those that say there is little 2M SSB activity why not stir some up???!!!???

Addendum to first post: a couple hours later:

It didn't take a light breeze more than an hour or so to wiggle the tree limb and allow the weight to drop down a bit further. I grabbed it with a pole and have completed that phase now.

But my question still stands. What is the recommended weight and line for this type work, and are there any recommended techniques to get the weight to drop down when friction of the tree limb tends to hold it?

I've done the same type shooting over the years, with good success rate.

I think 1 oz. is minimum, 1.5 oz. is better. I favor 30 lb. line.....and I only use monofilament. Mono is "slicker" and will slide over branches better than other types line.

As you found, patience helps.....give the wt. plenty of slack line, and leave it hang. It'll usually gradually drop lower and lower.

Also.....winter is better time to do this, when most trees have lost most of their foliage, especially in the North.

Hi Ed,

You've just experienced it. Wait. Gravity is your friend.

I use 1/16" braided nylon (so no curl is built in).

I've thrown it by hand (swinging the weight);
used a slingshot;
used a bow and arrow.

I usually scatter fill a large bucket so that the random loops do not
tangle when the weight goes into flight. There's nothing so shocking
as to find an arrow coming back with a snag caught on the nearest bush
(and isn't there always a bush near a tree?).

Always allow for free movement of the line afterwards. Don't tie it
firmly in place. Balance it with a counterweight, otherwise tree and
wind movement will wear something to failure.

What - no potato-gun ??
conduit, hair-spray, and a potato with fishing line.
spray into the conduit (closed at the other end except for a small hole.))
force potato into open end a ways.
put a match to the small hole. ka-pow
I heard it works pretty good, but sounds dangerous.

I use bow-and-arrow - with a fishing arrow.
that arrow is heavy enough to pull the line to the ground

OK Reg,

You are very patient and your time and expertise is appreciated.

Last night I looked at many web articles on loops, many of which had preamps. I was a little discouraged. Many were fed with coax, which seems a little odd, especially since some of these loops had secondary resonances in the MF or HF bands. It seems like a preamp with a little non linearity, some big MF signals nearby, and a feed line that isn't balanced is a bit of a disaster waiting to happen.

I know many of the HF radios in use have preamps that can be turned off (actually they are 20 db pads).

But, regardless of my receivers susceptibility to out of band signals, I would want to feed my receiver with balanced line...especially since it's much cheaper than coax and should help prevent the feed line from picking up signals.

So.....followed everything in your last message and it all seems so simple (now)....

Getting back to last nights study session. Spent a couple of hours in my 1987 ARRL Handbook and the remainder on the web looking at real life loops published there. The web aspect was really disappointingly devoid of technical jargon, it seems like most of the loop authors just threw something up and it seemed to work-the end:>: Do people just throw stuff up without understanding what they're doing, or do they understand and just fail to document the theory??

The Handbook tour was almost as bad. Very little was said about loops except that which applied to the full wave resonant loop and how it can serve as a driven element in a 1 lambda 'guad' type radiator. Other than the theoretical wavelength, the correction factor for wire diameter, there was not more than 2 paragraphs written with useful information on short loops such as I am trying to put up.

There was a question I had, perhaps I'm reading between the lines here tho....

YOU SAID:

>And even with an extremely long line any impedance mismatch loss will
>be negligible. So forget about 300-ohm balanced line and just use a
>simple not-tightly-twisted pair. NO IMPEDANCE MATCHING REQUIRED at
>either end. The size of the small coupling loop inside the main loop

>matches 50 ohms to a 50-ohm receiver. So ideally the line to the
>receiver could be 50-ohm coax. But, as I say, it doesn't matter.
>
>The size and shape of the small coupling loop is not critical. It can
>be circular or square. Theoretically, to match the loop to a 50-ohm
>receiver, it should have an area about 1/25th of the main loop area.
>To simplify construction the coupling loop can be made
>self-supporting.
>

With your statement above in mind, are you telling me (or inferring) that any loop can be made to match a 50 ohm line by controlling it's size (area inside the main loop compared to area inside the coupling loop)??

In rjeloop3, the different sized loops have different feed line impedances, ranging from about 200 to 4K ohms. I made my final selection based on the model that matched my existing 300 ohm twin lead. I know you said my line impedance doesn't matter much, and I agree, except that it upsets the tuned front end in the receiver a bit.

If it's possible to control this impedance of the small loop, what are the parameters I need to know to adjust mine to different values (other than those given by the software)??

I know you gave me the formula for matching to 50 ohms already. But, if this value can be controlled to customize the impedance, what do I need to know in order to make a match for other values?

For my planned 2 meter square loop, my area is 2 X 2 X 4 (2 meters by 2 meters times 4 turns), sm my total loop area is 16 square meters. From the information you gave me (above), I can feed the receiver with 50 ohm feed line if my coupling loop is 16/25 (or about .8 square meters)?

I know the matching isn't critical, but I'd like to have a good match for the sake of the front end tuned circuit in the receiver.

If you can't say without writing a book, please feel free to decline to answer. If you can give the answer briefly, I'd appreciate some comments however.

Hey Reg, was down in the basement where I keep the junk box and found a couple hundred feet of 4 conductor #24 solid copper cable. It's used for connecting telephones indoors. It's even cheaper than 300 ohm twin lead and I was wondering if I could/should use that as a feed line to the house??

Today I surveyed the loop location in the back yard, I have my solder and my 5/16" double weave rayon rope spool out and ready to go. My loop resonating capacitors should be here Wednesday. If all goes well, I could have a working installation by this time next week! Thing's

are looking up.

Also, Richard suggested a book about loops which I did not find in the library, or even in the reference section. I didn't price it yet, but I need to get some additional technical info. Do you have any suggestions for what to buy for books?? I don't need anything other than short loop theory (without heavy math).

Thanks to you and Richard and everyone else who commented in this thread, I learned a great deal.

Regards,

T

That is a good question. One site talked about using a directional
coupler, a few diodes and a scope to measure SWR but I didn't really
understand it all and it sounded like I needed a special diode that they
didn't give details on where to get.

What I am trying to do is tune home made antennas for wireless
networks. So I need to measure the SWR so I know when the antenna is
tunned as good as I can get it.

Hi Chris

If you are lucky, you will get some response to your post from some of the
very sharp antenna guys here. I'm not one of them.

I personally would have alot of learning to do if I wanted to know how to *match* an antenna if I knew only VSWR. I need to know the actual impedance at the load.
I have built a crude slotted line so I can measure complex load impedances at 137 MHz. That works OK, but certainly not perfect.
Let me know if you have access to tools that you can use to build a slotted line for 2.4 GHz.. A slotted line makes impedance matching fairly easy.

I suspect there are better ways to measure load impedance than building slotted lines for 2.4 GHz, I just dont yet understand them.

Jerry

I assume we're talking about WiFi cantennas here?

Anyway, Radio Shack has a $30 SWR meter which many people have pressed
into service at far higher than advertised frequencies. You'll need
to detour over to Fry's or someplace similar to get an adapter (or
stack of adapters) to get from the (comically large by wifi standards)
SO-239 to the reverse SMA or whatever is on your wifi gear.

2928. Re: Question on shooting a line

Newsgroup: rec.radio.amateur.antenna
Date: 2005-10-30 11:43:15 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11m9ceqjqnbs59b@corp.supernews.com>
Source record: 68325

I've been doing this on Field Day for a long time.

First off, I use about 6-8 pound test line. It's heavy enough to pull a nylon cord back over the tree, but light enough so it comes off smoothly and so I can get plenty of line on a reel.

Second, I use teardrop-shaped fishing weights (narrow at the line end), never round or pyramid. The latter types snag too readily if you have to pull the weight back up. Try dragging the weight across a weedy back yard if you need an illustration.

As for the weight itself -- over the years I slowly increased the weight to as much as 3 ounces, so it would drop freely through fairly dense pine and fir trees. But I had an increasing amount of trouble with the weight coming out of the pouch during the shot, leading to very short shots and even occasionally a cut elastic unless everything was just right. Dropping back with the weight cured the shooting problem, along with using a slingshot with wide spaced arms. I've settled on about 2 oz as the best compromise between trouble-free shooting and the ability to drop through the tree.

I never use this method for a home installation unless it's for no more than a few days -- the twine or even rope cuts into the tree, making it impossible to get down. This might not be as much of a problem with hardwood trees as it is for softer and pitchier conifers. Also, I've had people tell me that very heavy nylon monofilament is less prone to this -- I haven't tried it.

I believe a "Slotted Line" would be among the better ways to measure SWR
in this frequency range.

Ask Cecil or Roy, regular contributors to this list, for their advice.

I would recommend the Mini-Circuits ZABDC-25HP directional coupler ($89.95).
Do not use diode detectors. Mix the forward and reverse ports down to a low
frequency, of 10 MHz or so (phase information is preserved). View the
downconveted signals on a dual channel oscilloscope. Techincally you need
to low pass filter the downconverted signals, but the scope will not see the
higher frequency components.

Do not attempt to use SO-239 connectors at 2.5 GHz. Building a directional
coupler at 2.5 GHz requires track precision in the order of +/- 1/1000".
You will also need high quality PCB material such as RT Duroid.

Regards,

Frank

6 pound monofilament line is more than strong enough. I use that to pull up a nylon string, which in turn can pulll up anything. The secret is not to lay the line on the ground. A 1 inch twig is enough to spoil your day. First lay a drop cloth on the ground, and lay out the line on that. Some people on this newsgroup use a plastic bucket.

If you miss the right branch, don't try to pull the weight back up. Let it go all the way to the ground, cut off the weight, and then pull back the line.

I use a bow and arrow, with a small solid rubber ball fixed to the front of the arrow. I have one wire going between branches 70 feet up. It works better if you wait until the leaves are off the trees.

Hi All

I want to construct a backpack antenna that can be left on my rucksack and used when walking.

The plan is to have a FT817 on my waist and the antenna fitted to the rucksack. I been playing with a mobile antenna today and can not get the SWR down without trailing a wire. I don't want a wire trailing behind me.

Any ideas for a 2m antenna that can be left on a rucksack when walking and used for transmittion. Height is not a major problem but it has to realistic and robust.

Thanks
Steve

Take a look in the latest issue of the ARRL Antenna Book. Chapter 5 is devoted entirely to loop antennas, and the chapter includes information about small loops. At the end of the chapter is a nice sized bibliography.

Hi Steve

Many years ago I use to do early morning exercise walks in the mountain range immediately to the west of Sydney's metro area. As soon as I dropped off the western mountain edge all rptr sigs were still audible on my IC2A but they couldnt hear me.

I made up a 2M jpole out of 10mm aluminium and tied it to my backpack with rope and/or rubber straps. The thing wobbled a bit but stayed more or less vertical. The backpack was very floppy, a more rigid one would have been better. There was about a 1/2 metre metal extension from the base of the matching section to faciltate the rope binding. The thing was about 1.3 metres max height above my head.

I also built a 10W PA running off 12 D cell NiCd's. Worked very well until the constant battery pack flexing shorted something and the hot wiring melted a hole through the backpack pocket it was sitting in!

If the extra matching section length is an issue you might find other ways of end/voltage feeding the 1/2 wave. Lots of possibilities here. You could also use a fibreglass rod with 300 ohm ribbon tied to it in a jpole or slim jim form. Handy in a region of low flying trees.

Height on LOS frequencies is everything . Getting the antenna above your head will make a huge difference. Everyone thinks you are a extraterrestrial visitor too!

Your present mobile antenna will need a counterpoise. (aka groundplane) I suggest you discard the idea of using it unless you can get use to the trailing 1/4 wave wire(s). Maybe it would work by mounting the antenna on an extension so its base is about head height, then wrapping three ground radials down the sides of the backpack. You could make it more permanent by weaving the wire into the backpack itself.

Cheers Bob VK2YQA (in W5)

Hello to all, my name is Miguel, LU 6ETJ.

It is a pleasure to read this group. This topic is really an
interesting question...

Modestly I would want to point out the following thing:

Imagine an inner radiant spherical surface with a finite and uniform
density radiant energy.
Aim a directional antenna with a directivity of, for example, one
stereoradian on any direction.
How is it able to such an antenna to receive equal quantity of energy
of a smaller portion of the sphere than an antenna that is able to
receive the energy taken place by the entirety sphere?

Untranslated text for reference (my written english is a little poor
;>( ):

Hola a todos, mi nombre es Miguel LU 6ETJ.

Es un gusto leer este grupo. Este tópico es realmente una interesante
pregunta...

Modestamente desearía señalar lo siguiente:

Imagine la parte interior de una esfera radiante, con una densidad de
energia radiante finita y uniforme.
Apunte un antena direccional con una directividad de, por ejemplo, un
estéreo radian en cualquier dirección.
¿Cómo puede tal antena recibir igual cantidad de energía de una
porción menor de la superficie radiante, que una antena que es capaz
de recibir la energía producida por la totalidad de la esfera?
